1. Overview and Scope

1.1. Introduction

This device specification is compliant with the UPnP Device Architecture version 1.0. It defines a device type referred to herein as ManageableDevice, and a set of UPnP services that provide UPnP Device Management (DM) functions.

UPnP DM services can be used to add management operations to any UPnP device. Management includes such functions as troubleshooting, diagnostic, configuration and software/firmware image management. Section 2.3 defines the general architecture for deployment of these services, which provide functionality to:

- Perform basic management operations on a device using the BasicManagement service (refer to the Basic-Management service specification [BMS] for details).
- Configure a device using the ConfigurationManagement service (refer to the ConfigurationManagement service specification [CMS] for details).
- Manage software components on a device using the SoftwareManagement service (refer to the SoftwareManagement service specification [SMS] for details).

In addition, a set of generic configuration/status parameters, referred to as the UPnP DM Common Objects, is defined in ConfigurationManagement service [CMS], and are accessible via the actions defined in the ConfigurationManagement service. A ManageableDevice has to support these parameters (some are OPTIONAL) via the ConfigurationManagement service.

A full-featured UPnP DM device provides Control Points with the following capabilities:

- BasicManagement:
  - Reboot and/or reset the device;
  - Perform IP (Internet Protocol) layer, self-test diagnostics and bandwidth tests;
  - Retrieve status and content of device logs.

- ConfigurationManagement:
  - Check the configuration and status of a device;
  - Provision or configure devices.

- SoftwareManagement:
  - Manage software lifecycle on a device;
  - Update software components and firmware images.

The UPnP DM service specifications do not specify or restrict format and content of log files nor protocols for downloading software or firmware.

Regarding UPnP DM services deployment, there are two main methods:

- either by deploying a UPnP DM device with at least BasicManagement service and the ConfigurationManagement service (SoftwareManagement service is OPTIONAL),
or by deploying independently UPnP DM services ([BMS], [CMS] and [SMS]) as additional features of other types of UPnP device.

At last, Device Management operations can be protected by an OPTIONAL Security feature based on DeviceProtection:1 [DPS]. Actions that do not return sensitive information, change the device configuration, or affect normal device operation can always be invoked by all Control Points. If the Security feature is supported, other actions can only be invoked if the Control Point is appropriately authorized.

1.4. Notation

- In this document, features are described as Required, Recommended, or OPTIONAL as follows:

  The key words “MUST,” “MUST NOT,” “REQUIRED,” “SHALL,” “SHALL NOT,” “SHOULD,” “SHOULD NOT,” “RECOMMENDED,” “MAY,” and “OPTIONAL” in this specification are to be interpreted as described in [RFC 2119].

  These keywords are thus capitalized when used to unambiguously specify requirements over protocol and application features and behaviour that affect the interoperability and security of implementations. When these words are not capitalized, they are meant in their natural-language sense.

- Strings that are to be taken literally are enclosed in “double quotes”.

- Words that are emphasized are printed in italic.

- Data Model names and values, and literal XML, are printed using the data character style.

- Keywords that are defined by the UPnP DM Working Committee are printed using the forum character style.

- Keywords that are defined by the UPnP Device Architecture are printed using the arch character style.

- A double colon delimiter, “::”, signifies a hierarchical parent-child (parent::child) relationship between the two objects separated by the double colon. This delimiter is used in multiple contexts, for example: Service::Action(), Action()::Argument.
2. Device Definitions
The requirements in this section apply only when ManageableDevice is used. Section 2.3 defines the general architecture for deployment of the UPnP DM services.

2.1. Device Type
The following device type identifies a device that is compliant with this specification:

urn:schemas-upnp-org:device:ManageableDevice:2

2.2. Device Model
A ManageableDevice:2 MUST implement minimum version numbers of all REQUIRED embedded devices and services specified in the table below. A ManageableDevice:2 device can be either a Root device or can be Embedded within another UPnP device. A ManageableDevice:2 device can contain other standard or non-standard Embedded UPnP devices as well.

¹ R = Required, CR = Conditionally required, O = OPTIONAL, X = Non-standard.
² Prefixed by urn:upnp-organ:serviceld:
³ MUST support the UPnP DM Common Objects as defined in ConfigurationManagement service.
⁴ REQUIRED if the Security feature is supported.
2.3. Architecture

This section provides the general architectural concepts for the deployment of UPnP DM services, within ManageableDevice or within any other UPnP device.

Figure 2-1 shows the dependency diagram for ManageableDevice and for several other example UPnP devices. It can be seen that this diagram implies most of the ManageableDevice requirements of Table 2-1:

- **BasicManagement** [BMS] is required.
- **ConfigurationManagement** [CMS] is required (in order to access the required UPnP DM Common Objects).
- **SoftwareManagement** [SMS] is OPTIONAL.
- **DeviceProtection** [DPS] is OPTIONAL.

![Figure 2-1: Architecture Diagram](image-url)

Figure 2-1 illustrates the architecture of a ManageableDevice and also of three other UPnP devices:

- The first one implements only logging actions and so requires only BasicManagement. BasicManagement has an OPTIONAL dependence on the UPnP DM Common Objects (see [BMS] for details).
- The second one implements only software life-cycle actions and so requires only SoftwareManagement. SoftwareManagement has an OPTIONAL dependence on the Software Data Model.
• The third one requires access to some additional data models, and so requires only ConfigurationManagement.

The UPnP DM Common Objects define baseline configuration information for the device, which is accessible via the ConfigurationManagement service. When the ConfigurationManagement service is included in a UPnP device other than ManageableDevice, the UPnP DM Common Objects will not necessarily be supported; instead other specific data models might be provided by the UPnP device. If this is a standard UPnP device type, additional data models might also be defined by the corresponding UPnP Working Committee.

Since many other definitions of sets of parameters for device management (data models) are widely available in the industry, a mechanism for importing other data model definitions into the UPnP DM Data Model is also defined. Details about this mechanism can be found in [CMS]. This mechanism also specifies how data models from other UPnP working committees should be handled by the ConfigurationManagement service.

In addition to UPnP DM services, security feature may also be OPTIONALly integrated to provide control over which actions can be invoked and which resources can be manipulated. Each device, including ManageableDevice, can choose to support or not this feature. In any case, the security feature MUST support DeviceProtection service [DPS] (see chapter 2.4). To conclude, security feature is applicable independently to any service, for example only to ConfigurationManagement service in a full feature ManageableDevice.
2.4. Security considerations

2.4.1. Scope
The main security concern of Device Management is to protect against attack from malicious Control Points. Moreover, without Security, Control Points can invoke any actions that are exposed by UPnP devices. More specifically the Security feature addresses the following needs of different stakeholders:

- For the End Users
  - To prevent unauthorized Control Points from invoking device management actions;
  - To avoid Man In the Middle attacks by providing secure communication channels;
  - To be able to provide fine-grained management control by providing Roles and Access Control Lists;
  - To feel comfortable delegating home network management to a third party.

- For the Device Manufacturers
  - To prevent unauthorized Control Points from managing UPnP devices;
  - To allow manufacturers to have fine-grained specific management operations.

- For the Service Providers
  - To define rules in order to ensure that some specific actions and resources will only be managed by an authorized Control Point;
  - To allow multiple service providers each to manage their own area of interest, thereby minimizing the possible side effects.

2.4.2. Overview
Security feature is OPTIONAL. It provides authorization mechanism to permit invocation of actions and to allow access to resources. Indeed BasicManagement:2, ConfigurationManagement:2 and SoftwareManagement:2 actions can change the behaviour of the UPnP device:

- Reboot operation when the device is doing some important transaction may impact user experience;
- Firmware update when the device is performing some configuration changes or some other transactions may affect the device operation.
- Some Execution Units may not be started and stopped by any Control Points;
- Some subtrees of the device Data Model may not be modified by any Control Points.

To enable the OPTIONAL Security feature, a UPnP service MUST support DeviceProtection:1 service. [DPS] specification defines additional security procedures and methods that have to be implemented by a UPnP service.

2.4.3. Parent device and embedded devices
Security feature applies to services supported by a device and not the device itself. In order to protect a Service, at least one of the ancestor devices MUST contain a DeviceProtection:1 instance. The Service is protected by the DeviceProtection:1 that is in its nearest ancestor device.

Copyright UPnP Forum © 2012. All rights reserved.
2.4.4. Roles

DeviceProtection:1 defines three Roles: Public, Basic and Admin. For the purposes of securing a given UPnP DM service, a minimum set of two Roles MUST be implemented with the following definitions based on [DPS]:

- **Public**: this is the less restrictive Role. It provides open access and it is associated to non-secured sessions: any Control Point is implicitly considered to have this Role in addition to any other Roles that are explicitly assigned to it. If a Public Role is recommended for an action, it implicitly means that any other Role is also allowed to run the action. Note that it explicitly means that it allows access to any Control Point without the need to support security and DeviceProtection service.

- **Admin**: this is the most restrictive Role. It provides secured access to any action and argument values and to entire Data Model. Any Control Point with such Role MUST have the access rights to all the resources of the UPnP device. This Role MUST NOT be included in the restricted Role List.

The Role name Public and Admin MUST be implemented by UPnP DM services whenever OPTIONAL Security feature is enabled.

For the purpose of specifications, the three Roles described in DeviceProtection:1 will be used to illustrate the different security levels. The name of the Basic Role MAY be changed but the following SHOULD apply:

- **Basic Role** provides some level of security (more restrictive than Public) by at least requiring secured sessions. It is associated to some actions/argument values. The privileges assigned to this Role depend on the implementation and deployment choices. When OPTIONAL Basic Role is implemented, it SHOULD comply with the recommendation herein specified.

Specifies additional OPTIONAL Roles MAY be implemented to support other device management Security use cases:

- **dm:ThirdPartyAdmin**: if specified, this Role MUST be assigned to a third party (instead of Admin) that provides the device for management on behalf of the end user. The privileges assigned to this Role MUST be a subset of privileges of the Admin Role (possibly coincident). dm:UserAdmin: if specified, this Role MUST be assigned to the end user (instead of Admin) for local administration of the device. The privileges assigned to this Role MUST be a subset of privileges of the Admin Role (possibly coincident).

The decision to implement dm:ThirdPartyAdmin, dm:UserAdmin and a deployment scenario in terms of Roles for actions depends on the usage context or business model. For instance implementation choice may be linked to fact that a device is rented or owned by a user. Consequently there are different possible deployment models. For example:
The figure above shows different scenarios:

1. This illustrates a service provider (dm:ThirdPartyAdmin) rights to manage a rented device such as a home gateway, where
   - The dm:ThirdPartyAdmin privileges are less or equal to the Admin privileges.
   - The dm:UserAdmin privileges are less or equal to the dm:ThirdPartyAdmin privileges.
   - The Basic privileges are less or equal to dm:UserAdmin privileged.

2. This illustrates a user (dm:UserAdmin) rights to manage an owned devices, where
   - The dm:UserAdmin privileges are less or equal to the Admin privileges.
   - The dm:ThirdPartyAdmin privileges are less or equal to the dm:UserAdmin privileges.
   - The Basic privileges are less or equal to dm:ThirdPartyAdmin privileged.

3. This illustrate a case where a third party and a user have the right to manage sub-sets of a device, possibly with common sub-sets, where
   - Both The dm:UserAdmin and dm:ThirdPartyAdmin privileges are less or equal to the Admin privileges.
   - The dm:UserAdmin has some privileges that may be shared with the dm:ThirdPartyAdmin. Both Roles may have privileges that are not assigned to the other.
   - The Basic privileges are less or equal to dm:ThirdPartyAdmin and/or dm:UserAdmin privileged.

Other deployment models can be defined with only two administration Roles, either the couple {Admin; dm:ThirdPartyAdmin} or the couple {Admin; dm:UserAdmin}. In fact implementers are free to decide whenever to add OPTIONAL Role for recommended Roles or recommended Restricted Roles:

Copyright UPnP Forum © 2012. All rights reserved.
For example, in the \texttt{GetSupportedParameters()} action ([CMS]), the \texttt{dm:ThirdPartyAdmin} and \texttt{dm:UserAdmin} Roles could be recommended in the Restricted Role List (see chapter 2.4.5) because there might be part of the Data Model which must be hidden to both in a mutually exclusive way.

There could be a set of parameters that is accessible only to \texttt{dm:ThirdPartyAdmin} (and \texttt{Admin}), whereas another set of parameters is accessible only to \texttt{dm:UserAdmin} (and \texttt{Admin}). But, for some simpler implementation, a less restrictive requirement could be enough, having both the \texttt{dm:ThirdPartyAdmin} and \texttt{dm:UserAdmin} Roles in the Role List: therefore they both have complete access to all the supported parameters.

Due to the heterogeneous scenarios, [BMS], [CMS] and [SMS] specifications will not list OPTIONAL Roles such as \texttt{dm:ThirdPartyAdmin} and \texttt{dm:UserAdmin} for actions and will limit recommendations to the three mandatory Roles, \texttt{Public}, \texttt{Basic} and \texttt{Admin}, as defined by Device Protection.

In case \texttt{dm:ThirdPartyAdmin} and/or \texttt{dm:UserAdmin} are implemented, the hierarchy between the different Roles from the most to the less privileged MUST be:

1. \texttt{Admin}
2. \texttt{dm:ThirdPartyAdmin} or \texttt{dm:UserAdmin}
3. \texttt{Basic}
4. \texttt{Public}

To conclude, implementers are free to decide which Roles should be implemented when supporting Security feature. Only \texttt{Public} and \texttt{Admin} are MANDATORY, other intermediate OPTIONAL Role names depends on Security implementation requirements and there should usually not be a clear hierarchy interpreted from the Role names. Each UPnP DM service will provide the necessary actions to list unconditional and conditional actions that each Role is allowed to invoke.

Note that it is strongly suggested to respect the recommended propositions (e.g. security level to run actions) as they represent an appropriate implementation of a secured device management.

\subsection*{2.4.5. Role List and Restricted Role List}

\texttt{DeviceProtection:1} defines \texttt{Roles List} and \texttt{Restricted Role List}. As this is a key concept for UPnP DM Security feature, the following is a reminder of its usage as defined in [DPS] specification.

Actions that do not return sensitive information, change the device configuration, or affect normal device operation are referred to as \texttt{Non-Restrictable} actions and can always be invoked by all control points. For example, diagnostic actions that can facilitate interoperability, or actions that event a state variable that cannot be protected by \texttt{DeviceProtection:1}. All other actions are referred to as \texttt{Restrictable} actions.

If the OPTIONAL Security feature is not supported, all actions can be invoked by all control points. If the Security feature is supported, \texttt{Restrictable} actions can only be invoked if the control point is appropriately authorized.

The terms \texttt{Role List} and \texttt{Restricted Role List} are defined by \texttt{DeviceProtection:1}. Each action has an associated \texttt{Role List}; a control point that possesses a \texttt{Role} in the \texttt{Role List} can unconditionally invoke the action. The \texttt{Role} names in \texttt{Role List} have OR semantics (e.g. “\texttt{Admin Basic}”). This means that a Control Point only needs to be authorized with one of the \texttt{Roles in Role List} to use the action. The \texttt{Roles in Role List} are granted access for all argument values.

Some actions also have a \texttt{Restricted Role List}; a control point that does not possess a \texttt{Role} in the \texttt{Role List} but does possess a \texttt{Role} in the \texttt{Restricted Role List} might be able to invoke the action (it’s up to the action definition to specify this).

The \texttt{Public Role} is defined by \texttt{DeviceProtection:1}. All control points automatically possess the \texttt{Public Role}, and all control points can unconditionally invoke all actions that have a \texttt{Role List} of “\texttt{Public}”. Therefore:
• If the Security feature is not supported, behavior is the same as if the feature was supported and all actions had a Role List of “Public” and an empty Restricted Role List.

• Regardless of whether or not the Security feature is supported, all Non-Restrictable actions have a Role List of “Public” and an empty Restricted Role List.

For Restrictable actions, this specification defines RECOMMENDED values for the Role Lists and Restricted Role Lists. Device manufacturers are permitted to choose different values.

2.4.6. Access Control List

The DeviceProtection access control model is based on an access control list (ACL) that assigns Device-specific and service-specific Roles to Control Point and User Identities. Each Device maintains its own ACL, and there is no explicit support for automatically sharing or synchronizing ACLs across multiple Devices. Roles correspond to permissions to perform specific SOAP actions or to access resources (Data Model, deployment and execution units).

UPnP DM service specifications include RECOMMENDED Roles to perform actions, but Devices MAY ignore those recommendations. Therefore BasicManagement:2, ConfigurationManagement:2 and SoftwareManagement:2 services provide the ability to query a service to discover the Roles required to perform specific actions or access specific resource.

Note that ACL cannot be changed dynamically; consequently any ACL Data Model modification in an existing UPnP DM device will be a consequence of a software update or an implementation specific mechanism.

2.4.7. General Security Policies

If Public is the MANDATORY Role List, then TLS tunnel is OPTIONAL when invoking the action and the action is non-restrictable. This allows unsecured Control Point to access to Public actions and resources of a device.

2.4.8. Backward compatibility

Any UPnP DM version 2 device that supports OPTIONAL Security feature might reject an action invocation that would have been permitted by a given UPnP DM version 1 device.

This is not a backward compatibility issue since returned error codes are already defined in UDA (see [UDA]). UPnP DM version 2 and UPnP DM version 1 are based on UDA. Security error codes are used when (list is not exhaustive):
• action does not return information and CP role isn't appropriate;
• information returned is "all or nothing" and CP role isn't appropriate;
• information requested is supposed to be hidden to the CP role used to invoke the action.
2.5. Theory of Operation

After a Control Point discovers UPnP device implementing UPnP DM device or services within the home network, it can invoke various actions defined within services listed in Table 2-1: Device Requirements. In the following subsections, a set of basic usage scenarios are introduced.

All examples in this section are provided with reference to the ManageableDevice device type, but they apply also to other types of UPnP device that include the corresponding UPnP DM services.

2.5.1. Option 1: UPnP DM services contained within ManageableDevice

The following two figures illustrate the two main options for deploying ManageableDevice as a root device, Figure 2-2 outlines the minimum deployment option, where only required UPnP DM services are provided:

- The BasicManagement service (BMS) provides basic features for administration and diagnostics;
- The ConfigurationManagement service (CMS) provides management of UPnP DM Common Objects.

Figure 2-3 outlines the extended deployment option, where all UPnP DM services are provided:

- The SoftwareManagement service (SMS) targets an EE and adds management functions for firmware upgrade and software management.

2.5.2. Option 2: UPnP DM services included in other types of UPnP device

UPnP DM services are designed to be included in other types of UPnP device. The following figures illustrate some possible deployment options for UPnP DM services inside an arbitrary UPnP device.

Figure 2-4 below outlines the most general deployment option of the complete set of UPnP DM services within UPnP Device X (which also provides its own services):
- BMS, CMS and SMS provide the corresponding management features for UPnP Device X;

Figure 2-5: Example UPnP device including UPnP DM services

Figure 2-5 outlines a minimal deployment option, where only one UPnP DM service (BMS) is included within UPnP Device X (which also provides its own services):

- BMS provides basic management features for the targeted UPnP device.

Figure 2-6: Example UPnP device including BMS only

Figure 2-6 outlines another minimal deployment option, where only one UPnP DM service (CMS) is included within a UPnP Device X (which also provides its own services):

- CMS provides configuration management features for specific parameters defined for the targeted device (Device X Data Model);
- UPnP DM Common Objects can be OPTIONALy supported.

Figure 2-7: Example UPnP device including CMS only
If a standard UPnP device adopts this option, it can also define its own Data Model to be manipulated by CMS.

Figure 2-7 outlines another minimal deployment option, where only one UPnP DM service (SMS) is included within a UPnP Device X (which also provides its own services):

- SMS provides software management features for the targeted device;
- The UPnP DM Software Data Model as defined in SoftwareManagement service can beOPTIONALy supported (not shown in figure). In that case CMS will also be supported (not shown in figure).

2.5.3. Option 3: Multiple root devices

Figure 2-8 illustrates the deployment option where multiple root UPnP devices are available in a single physical device (product), and one of these is the ManageableDevice:

- UPnP Device X and Device Y provide their own functionality;
- UPnP ManageableDevice provides management features for either the physical device or the other UPnP root device(s): this choice depends upon the implementation or can be specified by the UPnP Working Committee defining such architecture for these UPnP devices.
2.5.4. Option 4: Embedded ManageableDevice

Figure 2-9 illustrates the deployment option where the ManageableDevice is embedded within another UPnP device:

![Diagram](image1)

Figure 2-10: UPnP ManageableDevice as embedded device

2.5.5. Example: Deployment of Device Protection in the root device

Figure 2-13 illustrates deployment scenario of Device Protection [DPS] in a root device:

![Diagram](image2)

Figure 2-11: An example of Security feature implementation in a root device

- Root device X supports a Security feature (DeviceProtection service) defined at root level. This Security feature (Service DPS) has a scope of the entire root device since there are no other DPS instances in embedded devices.

- Embedded device Y is using the Security feature defined at root level to secure its UPnP Device Management actions.

2.5.6. Example: Deployment of Device Protection in an embedded device

Figure 2-14 illustrates deployment scenario of Device Protection [DPS] in an embedded device:
2.5.7. Option 5: **ManageableDevice** embedding other UPnP devices

Figure 2-10 illustrates the deployment option where the **ManageableDevice** is embedding other UPnP devices:

- The UPnP **ManageableDevice** actions affect also the embedded UPnP devices;
- Indeed additional data models (not shown in the figure) can be added for addressing specific management requirements of the embedded devices.

2.5.8. Example: A Complex Deployment

Figure 2-11 is an example of a complex deployment where some of the previous deployment options are mixed, in order to get the desired combination and scope for the different device management domains:

- Each UPnP DM service targets its parent UPnP device.
Figure 2-14: An example of complex implementation with device management features

Appendix A: specification changes

Changes between specification document version 1 and version 2:

- Section 2.4 added: description of Security feature using DeviceProtection service.
- Section 2.5.5 added: example of Security implemented in a root device.
- Section 2.5.6 added: example of Security implemented in an embedded device.
- Section 3 added: DeviceProtection in the XML device description document.
