SoftwareManagement:2
Service Template Version 1.01
For UPnP Version 1.0
Status: Standardized DCP (SDCP)
Date: February 16th, 2012

This Standardized DCP has been adopted as a Standardized DCP by the Steering Committee of the UPnP Forum, pursuant to Section 2.1(c)(ii) of the UPnP Forum Membership Agreement. UPnP Forum Members have rights and licenses defined by Section 3 of the UPnP Forum Membership Agreement to use and reproduce the Standardized DCP in UPnP Compliant Devices. All such use is subject to all of the provisions of the UPnP Forum Membership Agreement.

THE UPNP FORUM TAKES NO POSITION AS TO WHETHER ANY INTELLECTUAL PROPERTY RIGHTS EXIST IN THE STANDARDIZED DCPS. THE STANDARDIZED DCPS ARE PROVIDED "AS IS" AND "WITH ALL FAULTS". THE UPNP FORUM MAKES NO WARRANTIES, EXPRESS, IMPLIED, STATUTORY, OR OTHERWISE WITH RESPECT TO THE STANDARDIZED DCPS, INCLUDING BUT NOT LIMITED TO ALL IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT AND FITNESS FOR A PARTICULAR PURPOSE, OF REASONABLE CARE OR WORKMANLIKE EFFORT, OR RESULTS OR OF LACK OF NEGLIGENCE.

1 Overview and Scope

This service definition is compliant with the UPnP Device Architecture version 1.0 [UDA1.0]. It defines a service type referred to herein as SoftwareManagement:2 service or, where the version number is not significant, SoftwareManagement service.

1.1 Introduction

Many devices in the home network (for example, TV, Camera, Media Server etc.) have embedded software or firmware that needs to be managed. The SoftwareManagement service is intended to provide control points with the ability to manage this embedded software or firmware.

The SoftwareManagement service enables a control point to:

- Install or Update software entities on a targeted Execution Environment.
- Uninstall software entities on a targeted Execution Environment.
- Start software entities on a targeted Execution Environment.
- Stop software entities on a targeted Execution Environment.
- Update device firmware.

The SoftwareManagement service does not:

- Mandate the protocol used for downloading the software entities
- Provide details of any particular Execution Environment

These operations can be protected by an OPTIONAL Security feature based on DeviceProtection:1 [DPS]. Actions that do not return sensitive information, change the device configuration, or affect normal device operation can always be invoked by all control points. If the Security feature is supported, other actions can only be invoked if the control point is appropriately authorized.

This specification frequently uses the term Parent Device. This refers to UPnP device/service sub-tree whose root is the UPnP device that contains the SoftwareManagement service instance. UPnP actions or other operations on a Parent Device SHOULD apply to all levels of this sub-tree, but SHOULD NOT apply to an embedded device that itself contains a SoftwareManagement service instance.

1.2 References

This section lists the references used in the UPnP DM specifications and includes the tag inside square brackets that is used for each such reference:

1.4 Notation

- In this document, features are described as Required, Recommended, or Optional as follows:

  The key words “MUST,” “MUST NOT,” “REQUIRED,” “SHALL,” “SHALL NOT,” “SHOULD,” “SHOULD NOT,” “RECOMMENDED,” “MAY,” and “OPTIONAL” in this specification are to be interpreted as described in [REQLEV].

  In addition, the following keywords are used in this specification:

  - PROHIBITED – The definition or behavior is an absolute prohibition of this specification. Opposite of REQUIRED.
  - CONDITIONALLY REQUIRED – The definition or behavior depends on a condition. If the specified condition is met, then the definition or behavior is REQUIRED, otherwise it is PROHIBITED.
  - CONDITIONALLY OPTIONAL – The definition or behavior depends on a condition. If the specified condition is met, then the definition or behavior is OPTIONAL, otherwise it is PROHIBITED.

  These keywords are thus capitalized when used to unambiguously specify requirements over protocol and application features and behavior that affect the interoperability and security of implementations. When these words are not capitalized, they are meant in their natural-language sense.

- Strings that are to be taken literally are enclosed in “double quotes.”

- Words that are emphasized are printed in italic.

- Data model names and values, and literal XML, are printed using the data character style.

- Keywords that are defined by the UPnP DM Working Committee are printed using the forum character style.

- Keywords that are defined by the UPnP Device Architecture are printed using the arch character style.

- A double colon delimiter, “::”, signifies a hierarchical parent-child (parent::child) relationship between the two objects separated by the double colon. This delimiter is used in multiple contexts, for example: Service::Action(), Action()::Argument.

1.4.1 Data Types

This specification uses data type definitions from two different sources. The UPnP Device Architecture defined data types are used to define state variable and action argument data types [UDA1.0]. The XML Schema namespace is used to define XML-valued action arguments [XML-SCHEMA-2] (including [CMS] data model parameter values).

For UPnP Device Architecture defined Boolean data types, it is strongly RECOMMENDED to use the value “0” for false, and the value “1” for true. However, when used as input arguments, the values “false”, “no”, “true”, “yes” may also be encountered and MUST be accepted. Nevertheless, it is strongly RECOMMENDED that all state variables and output arguments be represented as “0” and “1”.

For XML Schema defined Boolean data types, it is strongly RECOMMENDED to use the value “false” for false, and the value “true” for true. However, when used within input arguments, the values “false”, “true”
may also be encountered and MUST be accepted. Nevertheless, it is strongly RECOMMENDED that all XML Boolean values be represented as “0” and “1”.

XML elements that are of type xsd:anySimpleType (for example [CMS] data model parameter values) MUST include an xsi:type attribute that indicates the actual data type of the element value. This is a SOAP requirement.

1.4.2 Strings Embedded in Other Strings

Some string variables, arguments and other XML elements and attributes (including [CMS] data model parameter values) described in this document contain substrings that MUST be independently identifiable and extractable for other processing. This requires the definition of appropriate substring delimiters and an escaping mechanism so that these delimiters can also appear as ordinary characters in the string and/or its independent substrings.

This document uses such embedded strings in Comma Separated Value (CSV) lists (see section 1.5.1). Escaping conventions use the backslash character, “\” (character code U+005C), as follows:

a) Backslash (“\”) is represented as “\\”.

b) Comma (“,”) is represented as “\,” in individual substring entries.

c) Double quote (“"”) is not escaped.

This document also uses such embedded strings to represent XML documents (see section 1.5.2). Escaping conventions use XML entity references as specified in [XML] Section 2.4. For example:

a) Ampersand (“&”) is represented as “&amp;” or via a numeric character reference.

b) Left angle bracket (“<”) is represented as “&lt;” or via a numeric character reference.

c) Right angle bracket (“>”) usually doesn’t have to be escaped, but often is, in which case it is represented as “&gt;” or via a numeric character reference.

1.5 Derived Data Types

This section defines a derived data type that is represented as a string data type with special syntax. This specification uses string data type definitions that originate from two different sources. The UPnP Device Architecture defined string data type is used to define state variable and action argument string data types. The XML Schema namespace is used to define xsd:string data types. The following definition applies to both string data types.

1.5.1 Comma Separated Value (CSV) Lists

The UPnP DM services use state variables, action arguments and other XML elements and attributes that represent lists – or one-dimensional arrays – of values. [UDA1.0] does not provide for either an array type or a list type, so a list type is defined here. Lists MAY either be homogeneous (all values are the same type) or heterogeneous (values of different types are allowed). Lists MAY also consist of repeated occurrences of homogeneous or heterogeneous subsequences, all of which have the same syntax and semantics (same number of values, same value types and in the same order).

- The data type of a homogeneous list is string or xsd:string and denoted by CSV (x), where x is the type of the individual values.
The data type of a heterogeneous list is also **string** or **xsd:string** and denoted by CSV \((w, x [, y, z])\), where \(w\), \(x\), \(y\) and \(z\) are the types of the individual values, and the square brackets indicate that \(y\) and \(z\) (and the preceding comma) are optional. If the number of values in the heterogeneous list is too large to show each type individually, that variable type is represented as CSV (heterogeneous), and the variable description includes additional information as to the expected sequence of values appearing in the list and their corresponding types. The data type of a repeated subsequence list is **string** or **xsd:string** and denoted by CSV \((\{w, x, y, z\})\), where \(w\), \(x\), \(y\) and \(z\) are the types of the individual values in the subsequence and the subsequence MAY be repeated zero or more times (in this case none of the values are optional).

The individual value types are specified as [UDA1.0] data types or A_ARG_TYPE data types for **string** lists, and as [XML-SCHEMA-2] data types for **xsd:string** lists.

- A list is represented as a **string** type (for state variables and action arguments) or **xsd:string** type (within other XML elements and attributes).
- Commas separate values within a list.
- Integer values are represented in CSVs with the same syntax as the integer data type specified in [UDA1.0] (that is: optional leading sign, optional leading zeroes, numeric ASCII).
- Boolean values are represented in state variable and action argument CSVs as either “0” for false or “1” for true. These values are a subset of the defined Boolean data type values specified in [UDA1.0]: 0, false, no, 1, true, yes.
- Boolean values are represented in other XML element CSVs as either “0” for false or “1” for true. These values are a subset of the defined Boolean data type values specified in [XML-SCHEMA-2]: 0, false, 1, true.
- Escaping conventions for the comma and backslash characters are defined in section 1.4.2.
- The number of values in a list is the number of unescaped commas, plus one. The one exception to this rule is that an empty string represents an empty list. This means that there is no way to represent a list consisting of a single empty string value.
- White space before, after, or interior to any numeric data type is not allowed.
- White space before, after, or interior to any other data type is part of the value.

</tr>
<tr>
<td>CSV (string)</td>
<td>“”</td>
<td>Empty list. It is not possible to create a list containing a single empty string.</td>
</tr>
</tbody>
</table>

### 1.5.2 Embedded XML Documents

An XML document is a string that represents a valid XML 1.0 document according to a specific schema. Every occurrence of the phrase “XML Document” is italicized and preceded by the document’s root element name (also italicized), as listed in column 3, “Valid Root Element(s)” of Table 1-3, “Schema-related Information”. For example, the phrase SupportedDataModels XML Document refers to a valid XML 1.0 document according to the CMS schema [CMS-XSD]. Such a document comprises a single SupportedDataModels ... root element, optionally preceded by the XML declaration <?xml version="1.0" ...?>.

This string will therefore be of one of the following two forms:

“<SupportedDataModels ...>...</SupportedDataModels>”

or
Escaping conventions for the ampersand, left angle bracket and right angle bracket characters are defined in section 1.4.2.

For consistency with [UDA1.0] and for future extensibility, devices and control points MUST ignore the following in embedded XML documents:

- Any unknown XML elements and their sub elements or content,
- Any unknown attributes and their values,
- Any XML comments that they do not understand, and
- Any XML processing instructions that they do not understand.

### 1.6 Management of XML Namespaces in Standardized DCPs

UPnP specifications make extensive use of XML namespaces. This allows separate DCPs, and even separate components of an individual DCP, to be designed independently and still avoid name collisions when they share XML documents. Every name in an XML document belongs to exactly one namespace. In documents, XML names appear in one of two forms: qualified or unqualified. An unqualified name (or no-colon-name) contains no colon (“:”) characters. An unqualified name belongs to the document’s default namespace. A qualified name is two no-colon-names separated by one colon character. The no-colon-name before the colon is the qualified name’s namespace prefix, the no-colon-name after the colon is the qualified name’s “local” name (meaning local to the namespace identified by the namespace prefix).

Similarly, the unqualified name is a local name in the default namespace.

The formal name of a namespace is a URI. The namespace prefix used in an XML document is not the name of the namespace. The namespace name is globally unique. It has a single definition that is accessible to anyone who uses the namespace. It has the same meaning anywhere that it is used, both inside and outside XML documents. The namespace prefix, however, in formal XML usage, is defined only in an XML document. It must be locally unique to the document. Any valid XML no-colon-name may be used. And, in formal XML usage, no two XML documents are ever required to use the same namespace prefix to refer to the same namespace. The creation and use of the namespace prefix was standardized by the W3C XML Committee in [XML-NMSP] strictly as a convenient local shorthand replacement for the full URI name of a namespace in individual documents.

All of the namespaces used in this specification are listed in the Tables “Namespace Definitions” and “Schema-related Information”. For each such namespace, Table 1-2, “Namespace Definitions” gives a brief description of it, its name (a URI) and its defined “standard” prefix name. Some namespaces included in these tables are not directly used or referenced in this document. They are included for completeness to accommodate those situations where this specification is used in conjunction with other UPnP specifications to construct a complete system of devices and services. The individual specifications in such collections all use the same standard prefix. The standard prefixes are also used in Table 1-3, “Schema-related Information”, to cross-reference additional namespace information. This second table includes each namespace’s valid XML document root element(s) (if any), its schema file name, versioning information (to be discussed in more detail below), and a link to the entry in Section 1.2, “References” for its associated schema.

The normative definitions for these namespaces are the documents referenced in Table 1-3. The schemas are designed to support these definitions for both human understanding and as test tools. However, limitations of the XML Schema language itself make it difficult for the UPnP-defined schemas to accurately represent all details of the namespace definitions. As a result, the schemas will validate many XML documents that are not valid according to the specifications.

### Namespace Names, Namespace Versioning and Schema Versioning

The UPnP DM service specifications define several data structures (such as state variables and action arguments) whose format is an XML instance document that must comply with one or more specific XML namespaces. Each namespace is uniquely identified by an assigned namespace name. The namespaces that are defined by the DM Working Committee MUST be named by a URN. See Table 1-2 “Namespace Definitions” for a current list of namespace names. Additionally, each namespace corresponds to an XML schema document that provides a machine-readable representation of the associated namespace to enable automated validation of the XML (state variable or action parameter) instance documents.

Within an XML schema and XML instance document, the name of each corresponding namespace appears as the value of an `xmlns` attribute within the root element. Each `xmlns` attribute also includes a namespace prefix that is associated with that namespace in order to disambiguate (a.k.a. qualify) element and attribute names that are defined within different namespaces. The schemas that correspond to the listed namespaces are identified by URI values that are listed in the `schemaLocation` attribute also within the root element. (See Section 1.6.2)

In order to enable both forward and backward compatibility, namespace names are permanently assigned and MUST NOT change even when a new version of a specification changes the definition of a namespace. However, all changes to a namespace definition MUST be backward-compatible. In other words, the updated definition of a namespace MUST NOT invalidate any XML documents that comply with an earlier definition of that same namespace. This means, for example, that a namespace MUST NOT...
be changed so that a new element or attribute is required. Although namespace names MUST NOT change, namespaces still have version numbers that reflect a specific set of definitional changes. Each time the definition of a namespace is changed, the namespace’s version number is incremented by one.

Each time a new namespace version is created, a new XML schema document (.xsd) is created and published so that the new namespace definition is represented in a machine-readable form. Since an XML schema document is just a representation of a namespace definition, translation errors can occur. Therefore, it is sometime necessary to re-release a published schema in order to correct typos or other namespace representation errors. In order to easily identify the potential multiplicity of schema releases for the same namespace, the URI of each released schema MUST conform to the following format (called Form 1):

Form 1: "http://www.upnp.org/schemas/dm/" schema-root-name "-v" ver "-" yyyyymmdd ".xsd"

where

- schema-root-name is the name of the root element of the namespace that this schema represents.
- ver corresponds to the version number of the namespace that is represented by the schema.
- yyyyymmdd is the year, month and day (in the Gregorian calendar) that this schema was released.

Table 1-3 “Schema-related Information” identifies the URI formats for each of the namespaces that are currently defined by the UPnP DM Working Committee.

As an example, the original schema URI for the “cms” namespace might be “http://www.upnp.org/schemas/dm/cms-v1-20091231.xsd”. If the UPnP DM service specifications were subsequently updated in the year 2010, the URI for the updated version of the “cms” namespace might be “http://www.upnp.org/schemas/dm/cms-v2-20100906.xsd”.

In addition to the dated schema URIs that are associated with each namespace, each namespace also has a set of undated schema URIs. These undated schema URIs have two distinct formats with slightly different meanings:

Form 2: “http://www.upnp.org/schemas/dm/” schema-root-name “-v” ver “.xsd”

Form 3: “http://www.upnp.org/schemas/dm/” schema-root-name “.xsd”

Form 2 of the undated schema URI is always linked to the most recent release of the schema that represents the version of the namespace indicated by ver. For example, the undated URI “…/dm/cms-v2.xsd” is linked to the most recent schema release of version 2 of the “cms” namespace. Therefore, on September 06, 2010 (20100906), the undated schema URI might be linked to the schema that is otherwise known as “…/dm/cms-v2-20100906.xsd”. Furthermore, if the schema for version 2 of the “cms” namespace was ever re-released, for example to fix a typo in the 20100906 schema, then the same undated schema URI (“…/dm/cms-v2.xsd”) would automatically be updated to link to the updated version 2 schema for the “cms” namespace.

Form 3 of the undated schema URI is always linked to the most recent release of the schema that represents the highest version of the namespace that has been published. For example, on December 31, 2009 (20091231), the undated schema URI “…/dm/cms.xsd” might be linked to the schema that is otherwise known as “…/dm/cms-v1-20091231.xsd”. However, on September 06, 2010 (20100906), that same undated schema URI might be linked to the schema that is otherwise known as “…/dm/cms-v2-20100906.xsd”. When referencing a schema URI within an XML instance document or a referencing XML schema document, the following usage rules apply:

- All instance documents, whether generated by a service or a control point, MUST use Form 3.
• All UPnP DM published schemas that reference other UPnP DM schemas MUST also use Form 3.

Within an XML instance document, the definition for the schemaLocation attribute comes from the XML Schema namespace "http://www.w3.org/2002/XMLSchema-instance". A single occurrence of the attribute can declare the location of one or more schemas. The schemaLocation attribute value consists of a whitespace separated list of values that is interpreted as a namespace name followed by its schema location URL. This pair-sequence is repeated as necessary for the schemas that need to be located for this instance document.

In addition to the schema URI naming and usage rules described above, each released schema MUST contain a version attribute in the <schema> root element. Its value MUST correspond to the format:

```
ver "-" yyyyMMdd
```

where ver and yyyyMMdd are described above.

The version attribute provides self-identification of the namespace version and release date of the schema itself. For example, within the original schema released for the "cms" namespace (.../cms-v1-20091231.xsd), the <schema> root element might contain the following attribute: version="1-20091231".

### 1.6.2 Namespace Usage Examples

The schemaLocation attribute for XML instance documents comes from the XML Schema instance namespace “http://www.w3.org/2001/XMLSchema-instance”. A single occurrence of the attribute can declare the location of one or more schemas. The schemaLocation attribute value consists of a whitespace separated list of values: namespace name followed by its schema location URL. This pair-sequence is repeated as necessary for the schemas that need to be located for this instance document.

**Example 1:**

Sample CMS XML Instance Document. Note that the references to the UPnP DM schemas do not contain any version or release date information. In other words, the references follow Form 3 from above. Consequently, this example is valid for all releases of the UPnP DM service specifications.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<cms:ParameterValueList
xmlns:cms="urn:schemas-upnp-org:dm:cms"
xmns:xsi="http://www.w3.org/2001/XMLSchema-instance"
x:schemaLocation="urn:schemas-upnp-org:dm:cms
     http://www.upnp.org/schemas/dm/cms.xsd">
  <Parameter>
    <Path>...</Path>
    <Value>...</Value>
  </Parameter>
  ...
</cms:ParameterValueList>
```

### 1.7 Vendor-defined Extensions

Whenever vendors create additional vendor-defined state variables, actions or other XML elements and attributes, their assigned names and XML representation MUST follow the naming conventions and XML rules as specified in [UDA1.0], Section 2.5, “Description: Non-standard vendor extensions”.

2 Service Modeling Definitions

2.1 Service Type

The following service type identifies a service that is compliant with this template:

2.2 Key Concepts

This section is added to describe some normative requirements for the SoftwareManagement Service.

2.2.1 Software entities

Two software entities are defined by the SoftwareManagement service:

- **Deployment Unit (DU):** A DU is an entity which packages resources such as library files, executable files, configuration files, jar files, bundles or assemblies. This entity can be individually installed, uninstalled and updated. Each DU is identified using a unique identifier DUID.

- **Execution Unit (EU):** A EU is an entity such as a service, script, software component or MIDlet. It can individually be started or stopped. Once started an EU becomes active, e.g., provides services, until it is stopped. EUs only appear after the installation or update of DUs. Each EU is linked to a unique DU. A DU can embed multiple EUs. Each EU is identified using a unique identifier EUID.

Actions pertain to one of these two entities, e.g., Install(), Update() and Uninstall() pertain only to DUs.

2.2.2 Software Data Model

SMS defines an OPTIONAL Software Data Model. This is defined in /UPnP/DM/Software/data model sub-tree which contains details of DUs and EUs. Implementations which choose to provide additional details to the control point will do so by implementing the Software Data Model and a CMS to provide access to the data model. Alternatively some implementations use getDUInfo() and getEUInfo() actions instead of implementing Software Data Model. More details about the supported Parameters for the DU and EU are presented in Section 6.

2.2.3 Lifecycle Management

2.2.3.1 Deployment Unit lifecycle management

A DU can be installed, updated and uninstalled using the Install(), Update() and the Uninstall() actions respectively.

The allowed values for DU state are (see Figure 2-1):

- **Installing:** represents a transitory state while the DU is being installed.

- **Unresolved:** represents a stable state in which the DU is installed but some of its dependencies are missing.
Installed: represents a stable state in which the DU is currently installed and all the needed dependencies, if any, are resolved.

Uninstalling: represents the transitory state while the DU is being uninstalled.

Uninstalled: represents a stable state in which the DU has been uninstalled.

Figure 2-1: DU state diagram

If the Software Data Model is implemented, the new DU state (a result of the execution of those actions) MAY be reflected into the data model as a read-only parameter (see Section 6: Software Data Model):

/UPnP/DM/Software/DU/#/State

Two types of transitions are depicted in Figure 2-1, i.e., explicit transitions and automatic transitions. Explicit transitions are triggered by the request of a software management action. Such a request can be made by invoking a SMS action or any external API. The remainder of this section only describes the explicit transitions triggered by the call of SMS actions.

The Installing state can be reached by calling the Install() or the Update() action.

The Installed state is reached as an automatic transition from the Installing or the Unresolved state when the installation succeeds.

The Unresolved state is reached as an automatic transition from the Installing state when the operation completes but some dependencies are not currently resolved.

The Uninstalling state can be reached by calling the Uninstall() action on a DU which is in Unresolved or Installed state.

The Uninstalled state can be reached as an automatic transition from the Uninstalling state when the Uninstall() action completes.

2.2.3.2 Execution Unit lifecycle management

For an EU there is need for two distinct states called the Requested State and Running State.

Copyright UPnP Forum © 2012. All rights reserved.
When a control point requests an EU to \texttt{Start()}, it will expect the EU to be \texttt{Active}. Similarly when a control point requests an EU to \texttt{Stop()}, it will expect the EU to be \texttt{Inactive}. These two states “\texttt{Active}” and “\texttt{Inactive}” are called the Requested states from a control points view. But as per Parent Device, the actual EU state can be \textit{Starting, Running, Stopping} and \textit{Stopped}. These are called the Running States.

The \textit{Requested State} is defined according to what action is called on the EU.

The allowed values for Requested State are:

- \texttt{Active}: The value is set to \texttt{Active} when the \texttt{Start()} action is called.
- \texttt{Inactive}: The value is set to \texttt{Inactive} when the \texttt{Stop()} action is called.

If Software Data Model is implemented, the EU’s Requested State MAY be reflected by the read-only Parameter named (see \texttt{Section 6 Software Data Model}):

\texttt{/UPnP/DM/Software/DU/###/EU/###/RequestedState}

If the Software Data Model is implemented, the EU behaviour MAY be managed by two optional Parameters (see \texttt{Section 6 Software Data Model}):
/UPnP/DM/Software/DU/#/EU/#/AutoStart
/UPnP/DM/Software/DU/#/EU/#/AutoRestart

**AutoStart**: When set to 1 and if the Start() action is called at least once i.e. when the EU’s Requested State is **Active**, this indicates that the EU MUST be automatically started when the Parent Device boots. The **AutoStart** Parameter relies on the Execution Environment (EE) ability /UPnP/DM/Software/Capabilities/AbleToAutoStart to autonomously start EUs at boot time. When the Requested State of EU is **Inactive**, the **AutoStart** MUST be ignored.

**AutoRestart**: When set to 1 and if the EU’s Requested State is **Active**, this indicates that the EU will be restarted each time it is stopped by any other means than the Stop() action. The **AutoRestart** Parameter relies on the EE's ability /UPnP/DM/Software/Capabilities/AbleToAutoRestart to implement a mechanism such as a watchdog. **AutoRestart** Parameter has no effect at boot time.

The initial value for both the parameters is provided by the DU. Both Parameters are only relevant when the Requested State value is **Active**.

The **Running State** is defined according to what is currently happening on the targeted EE.

**Running State** allowed values are:

- **Stopped**: the EU is observed as stopped on the EE.
- **Stopping**: represents the transitory state while the EU is being stopped.
- **Running**: the EU is observed as running on the EE.
- **Starting**: represents the transitory state while the EU is being started.

If Software Data Model is implemented, the EU's **Running State** MAY be reflected by the read-only Parameter named (see Section 6 Software Data Model):

/UPnP/DM/Software/DU/#/EU/#/RunningState

### 2.2.4 Firmware

Some specific EEs define the notion of firmware. Firmware corresponds to a basic piece of software including a bootloader; without the baseline firmware installed, the device might not function. Several firmware images could be present at the same time, but only one is used at boot time. This one is called the primary firmware. DUID and EUID 0 are reserved for identifying this primary firmware.

### 2.2.5 Asynchronous actions

Software management operations (e.g., the start of an EU) are expected to take a significant length of time to execute. In particular, it cannot be assumed that a given operation will complete within the 30 seconds allowed by the [UDA1.0]. Therefore, every operation is done asynchronously: an action initiates the operation and an **OperationID** is immediately returned. Events associated with the **OperationIDs** state variable indicate the end of the operation to the service subscribers. Other related information SHOULD be notified in the same event message, i.e., the modified **DUIDs**, **EUIDs**, **ActiveEUIDs** lists.
2.2.6 Software entity dependency management

Software entities on a particular EE MAY have dependencies on each other; the ability for an EE to intelligently manage these dependencies is implementation (or EE) specific.

A control point can know about the dependency handling capability of a Parent Device in two ways:

- either by calling any action like `Install()/Start()` and checking its response or
- by retrieving the value of the
  `/UPnP/DM/Software/Capabilities/AbleToHandleDUDependency` and
  `/UPnP/DM/Software/Capabilities/AbleToHandleEUDependency` Parameters in the Software Data Model (if it is supported).

SMS actions have a Boolean argument called `HandleDependencies` which a control point uses to indicate to the device if it wants the device to handle dependencies automatically or if the control point itself will take care of the dependency handling. If an implementation can not honor `HandleDependencies` request, it MUST return an error. If a device does not return any error for `HandleDependencies`, the device MUST honor the `HandleDependencies` request and accordingly MUST either handle dependencies on its own when `HandleDependencies` is 1 and MUST NOT handle dependencies on its own when `HandleDependencies` is 0.

Alternatively a control point can check the dependency handling capability

```
“/UPnP/DM/Software/Capabilities/AbleToHandleDUDependency” and
“/UPnP/DM/Software/Capabilities/AbleToHandleEUDependency” Parameters of a
device in the Software Data Model. If the capability is 0 and a control point invokes an action with
HandleDependencies argument equal to 1, then the device MUST return an error. In other words if the
capability is 0 then a control point cannot control the dependency handling of this device. In that case a
control point MUST handle the dependencies on its own. But if the capability is 1 and a control point
invokes an action with HandleDependencies as 0, then the device, despite having the ability to handle
dependencies, it MUST NOT try to handle dependencies on its own. If, however the capability is 1 and a
control point invokes an action with HandleDependencies as 1, then the device MUST try to handle
dependencies.
```

All the actions that have “HandleDependencies” as an argument MUST comply with the above requirements. The exact details of what a dependency is and how and what are the requirements to handle the dependencies are implementation (or EE) specific. The DU dependencies and EU dependencies could have different semantics in different implementations.

If some dependencies of a DU are not satisfied for whatever reason, the DU MUST be assigned the Unresolved state (see Figure 2-1). If all the dependencies are successfully installed, the DU state is set to Installed. In both scenarios, all the EUs will be in the Inactive state.

2.2.7 Security

Actions that do not return sensitive information, change the device configuration, or affect normal device operation are referred to as Non-Restrictable actions and can always be invoked by all control points.

All other actions are referred to as Restrictable actions. If the OPTIONAL Security feature (based on DeviceProtection:1 [DPS]) is not supported, all actions can be invoked by all control points. If the Security feature is supported, Restrictable actions can only be invoked if the control point is appropriately authorized. Table 2-10 specifies which actions are Non-Restrictable and Restrictable.

The terms Role List and Restricted Role List are defined by DeviceProtection:1. Each action has an associated Role List; a control point that possesses a Role in the Role List can unconditionally invoke the action. Some actions also have a Restricted Role List; a control point that does not possess a Role in the

Copyright UPnP Forum © 2012. All rights reserved.
Role List but does possess a Role in the Restricted Role List might be able to invoke the action (it’s up to the action definition to specify this).

The Public Role is defined by DeviceProtection:1. All control points automatically possess the Public Role, and all control points can unconditionally invoke all actions that have a Role List of “Public”. Therefore:

- If the Security feature is not supported, behavior is the same as if the feature was supported and all actions had a Role List of “Public” and an empty Restricted Role List.
- Regardless of whether or not the Security feature is supported, all Non-Restrictable actions have a Role List of “Public” and an empty Restricted Role List.

For Restrictable actions, this specification defines RECOMMENDED values for the Role Lists and Restricted Role Lists. Device manufacturers are permitted to choose different values.

2.2.7.1 SoftwareManagement:2 access control data

The previous section explained that, when the Security feature is supported, Restrictable actions can have Restricted Role Lists and that, for such actions, a control point that does not possess a Role in the Role List but does possess a Role in the Restricted Role List might be able to invoke the action. This decision is made by consulting the SoftwareManagement:2 access control data.

Section 2.3.21 specifies SoftwareManagement:2 access control data syntax. To re-iterate, this access control data is relevant only for Restrictable actions, and only for control points that do not possess Roles in the Role List but do possess Roles in the Restricted Role List.

- If there is no access control entry for a given action, the access control decision is made as described in the description of the action in question. For example, the description of the Stop() action states that the control point which started a particular EU can always stop it, and this rule applies regardless of whether the access control data contains an entry for Stop().
- If there are one or more access control entries for a given action, access is permitted if the conditions stated in the action description are met, and if any of the action’s filters match (and the control point possesses a Role in the corresponding Role List).

An example access control data is as below:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<sms:ACL xmlns:sms="urn:schemas-upnp-org:dm:sms"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="urn:schemas-upnp-org:dm:sms
  http://www.upnp.org/schemas/dm/sms.xsd">
  <ACLEntry>
    <Action>Install</Action>
    <Filter>DUType="Application"</Filter>
    <Roles>Basic</Roles>
  </ACLEntry>
  <ACLEntry>
    <Action>Start</Action>
    <EUID>5</EUID>
    <Roles>Basic</Roles>
  </ACLEntry>
  <ACLEntry>
    <Action>Update</Action>
  </ACLEntry>
</sms:ACL>
```

Copyright UPnP Forum © 2012. All rights reserved.
Given the example as above and the action Role Lists and Restricted Role Lists have the values as recommended in Table 2-10, the following access control decisions would be made:

- A control point possessing the **Admin** Role will be unconditionally permitted to invoke all actions (because the Role List permits this).

- A control point possessing the **Basic** Role will be permitted to invoke the **Install()** action only if the **DUType** argument has the value “**Application**” (because the access control data specifies this).

- A control point possessing the **Basic** Role will be permitted to invoke the **Start()** action only if the **EUID** value is “5” (because the access control data specifies this).

- A control point possessing the **Basic** Role will be permitted to invoke the **Update()** action only if the filter criteria (**Type** argument value is “**Firmware**” and **DUOwner** is “**TI**”) is satisfied (because the access control data specifies this).

- A control point possessing the **Basic** Role will be permitted to invoke the **GetDUIDs()** action without any restriction.

- A control point which installed a DU MUST be unconditionally permitted to uninstall that particular DU (because the **Uninstall()** action description states this). In a similar way a control point which started an EU MUST be unconditionally permitted to stop that particular EU (because the **Stop()** action description states this).

Note that it is never necessary for an access control data entry to include the **Admin** Role in its Role List, because, as stated in [DEVICE] section 2.4.4, the **Admin** Role always grants full access to all actions.
### 2.3 State Variables

1 R = REQUIRED, O = OPTIONAL, CR = CONDITIONALLY REQUIRED, X = Non-standard.

2 CSV stands for Comma-Separated Value list. The type between brackets denotes the UPnP data type used for the elements inside the list (section 1.5.1).

3 REQUIRED if the Security feature is supported.

### 2.3.1 OperationIDs
Comma-separated list of operation identifiers. It stores the OperationID list of Requested and InProgress operations.

This state variable is evented to notify control points when software management operations are requested or finished. When a software management operation is requested, its OperationID is added to the OperationIDs list. An operation is in the Requested state when an asynchronous action is successfully called. When the operation ends, its OperationID is removed from the OperationIDs list. An operation ends in the Completed or Error state when all the managed software entities reach a stable state.
2.3.2 **DUIDs**

Comma-separated list of the DUIDs for all unresolved or installed DUs.

This state variable is evented to notify control points when new DUs enter the *Unresolved* or *Installed* or *Uninstalled* states. When an install operation is successfully completed, every new *DUID* that appears is added to the **DUIDs** list. When an *Uninstall()* operation is successfully completed, every associated *DUID* is removed from the **DUIDs** list. The DUID 0 is reserved to identify the primary firmware, i.e., a firmware the physical device is booting on.

2.3.3 **EUIDs**

Comma-separated list of the EUIDs for all EUs.

This state variable is evented to notify control points when new EUs appear with the installation of DUs and when they disappear with the uninstallation of related DUs. When an *Install()* operation is successfully completed, every new *EUID* that comes into existence is added to the **EUIDs** list. When an *Uninstall()* operation is successfully completed, every associated *EUID* is removed from the **EUIDs** list. The EUID 0 is reserved to identify the primary firmware, i.e., the firmware the physical device is booting on.

2.3.4 **ActiveEUIDs**

Comma-separated list of the EUIDs for all EUs that have explicitly been requested to start using the *Start()* action.

This state variable stores the *EUID* list of *Active* EUs. The elements in this list are contained in **EUIDs** list. It is evented to notify control points when EUs become *Active* and when they become *Inactive*. A *EUID* enters in the **ActiveEUIDs** list when the EU is successfully requested to start using the *Start()* action. A *EUID* leaves the **ActiveEUIDs** list when the EU is successfully requested to stop by the *Stop()* action.

2.3.5 **RunningEUIDs**

Comma-separated list of the EUIDs for all EUs that are currently running.

This state variable stores the *EUID* list of *Running* EUs. The elements in this list are contained in **EUIDs** list. It is evented to notify control points when EUs become *Running* and when they become *Stopped*. A *EUID* enters in the **RunningEUIDs** list when it is observed as running, i.e., is currently running whatever the means used to start it, i.e., by an explicit call of the *Start()* action or any other EE specific means. A *EUID* leaves the **RunningEUIDs** list when the EU is no more observed as running, i.e., is NOT currently running.

2.3.6 **ErrorEUIDs**

Comma-separated list of the EUIDs which are currently in an error state.

This state variable stores the *EUID* list of Error EUs. The elements in this list are contained in **EUIDs** list. It is evented to notify control points when EUs enter and leave *Error* state. The detailed error information MAY be retrieved by a control point from the *Software Data Model* Section 6 *Software Data Model*.

2.3.7 **A_ARG_TYPE_Boolean**

A boolean argument.
2.3.8  **A_ARG_TYPE_String**
A string argument.

2.3.9  **A_ARG_TYPE_ID**
This state variable is introduced to provide type information for *OperationID*, *DUID* and *EUID* arguments in various actions. It is an unsigned integer.

2.3.10 **A_ARG_TYPE_IDs**
Comma-separated list of the IDs.

This state variable is introduced to provide type information for *TargetedIDs* argument in the *GetOperationInfo* action.

2.3.11 **A_ARG_TYPE_OperationState**
This state variable is introduced to provide type information for the *OperationState* argument in the *GetOperationInfo* action. Allowed values are: *Requested*, *InProgress*, *Completed*, *Error* (see Figure 2-4).

The *Requested* state is reached when an operation is created. The operation stays in this state until the *Parent Device* is able to process it. One reason an operation could be delayed is the execution of a previously requested operation.

Once the *Parent Device* is able to process the operation the operation state is set to *InProgress*. It will stay in this state until the operation completes successfully or fails.

All the time an operation is in *Requested* or *InProgress* state, its *OperationID* is stored in the *OperationIDs* list (see 2.3.1).

2.3.12 \textbf{A\_ARG\_TYPE\_URI}\footnote{Copyright UPnP Forum © 2012. All rights reserved.} 
This state variable is introduced to provide type information for \texttt{URI} argument in various actions. The value of a URI can also be an empty string ("") and actions describe it.

2.3.13 \textbf{A\_ARG\_TYPE\_Action}\footnote{Copyright UPnP Forum © 2012. All rights reserved.} 
This state variable is introduced to provide type information for the \texttt{Action} argument in the \texttt{GetOperationInfo()} action. Allowed values are names of defined software management actions: \texttt{Install}, \texttt{Update}, \texttt{Uninstall}, \texttt{Start}, \texttt{Stop} and the names of any vendor-specific asynchronous actions (see Section 2.2.5).

\end{tabular}
\caption{AllowedValueList for \texttt{A\_ARG\_TYPE\_Action}}
\end{table}
2.3.14 **A_ARG_TYPE_ErrorDescription**

This state variable is introduced to provide type information for the `ErrorDescription` argument in the `GetOperationInfo()` action. Allowed values are names describing the source of the failure of an operation:

- `Error_None`: no error to be described.
- `Error_ConcurrentAccess`: multiple concurrent accesses to the same resource.
- `Error_MissingDependency`: some dependency related error
- `Error_Network`: communication failed because of a network failure.
- `Error_CorruptedFile`: the file currently accessed is invalid for reading.
- `Error_StorageFull`: no space available on the persistent storage.
- `Error_Other`: all other specific errors.
- Vendor-specific values that have to be considered as an error case

2.3.15 **A_ARG_TYPE_DUType**

This state variable is introduced to provide type information for `DUType` arguments in various actions. SMS actions use input argument of type `A_ARG_TYPE_DUType` to indicate the type of the targeted DU.

Allowed types for a DU:

- `Firmware`: a DU which is a firmware
- `Application`: a DU which is an application for the targeted EE
- `Configuration`: a DU which contains configuration data
- `Other`: a DU which is of any other type
- Vendor-specific values

2.3.16 **A_ARG_TYPE_Name**

This state variable is introduced to provide type information for `DUName` and `EUName` arguments in various actions. The format of this value is EE specific.

2.3.17 **A_ARG_TYPE_Version**

This state variable is introduced to provide type information for `DUVersion` and `EVersion` arguments in various actions. The format of this value is EE specific.

2.3.18 **A_ARG_TYPE_DUState**

This state variable is introduced to provide type information for the `DUState` argument in the `GetDUInfo()` action. See section 2.2.3.1.

2.3.21 A_ARG_TYPE_ACL

The XML document containing SoftwareManagement:2 access control data. This is a list of zero or more action ACLs, each of which specifies a filter expression and a set of associated Roles. See section 2.2.7.1 for an explanation on how the ACL Data is used for making access control decisions.

Note that ACLs are only provided for actions that have non-empty Restricted Role Lists. For such actions, the ACL filter expressions determine, for control points that possess a given Role, which action argument, DUID/ EUID, DUMetadata/ EUMetadata values will permit the action to be invoked.

The normative XML Schema definition is illustrated in Section 4.

A DU comes into existence in a device by the virtue of installing it. So for the first time when a DU is getting installed there is no DUID to identify it. The following are the list of DUMetadata that MUST be supported:

- M_DUType: Type of DU as defined in Software Data Model
- M_DUVersion: Version of DU as defined in Software Data Model
- M_DUName: Name of DU as defined in Software Data Model
- M_DUCreator: Creator of a particular DU represented as a string
- M_DUOwner: Owner of a particular DU represented as a string

The EU MAY support the following list of EUMetadata:

- M_EUName: Name of EU as defined in Software Data Model
- M_EUVersion: Version of EU as defined in Software Data Model
- M_EUCreator: Creator of a particular EU represented as a string
- M_EUOwner: Owner of a particular EU represented as a string

The filter for DU actions can use only DUMetadata. But the filter for EU actions can use both DUMetadata and EUMetadata.

The decision on when to do the access control check for a DU operation is implementation dependent. But some of these checks can be done before downloading the DU and some can be done only after downloading the DU. For example, the access control checks based on the argument values can be done before downloading the DU and the access control checks based on DUMetadata can be done after downloading the DU. An EU comes into existence in a device by the virtue of corresponding DU installation.

An example of a filter expression for Install() action is as below:

<Filter>DUType="Firmware" and M_DUOwner="TI"</Filter>
The above expression uses both argument and metadata based filter expression. It is used to identify all the
DUs of type “firmware” and owned by “TI”. This filter expression when used in an ACL means that it will
apply over all firmware which are owned by TI.

The filter expression syntax is based on XPath 1.0 [XPATH-1.0]. All the lexical rules, operator
precedence, type conversions etc are as specified by XPath, but the concept of “path” is replaced with the
much simpler concept of “action argument or DU/EU metadata”.

The following EBNF-style syntax [EBNF] MUST be supported:

1. Filter ::= Expr
2. Expr ::= EqualityExpr | FunctionCall
3. EqualityExpr ::= ArgumentName | DUMetadata | EUMetadata “=” Constant
   | ArgumentName | DUMetadata | EUMetadata “!”= Constant
4. Constant ::= Literal (string in double quotes)
   | Number (signed or unsigned integer)
5. FunctionCall ::= “contains(” ArgumentName “,” Literal “)"

This is sufficient to support the requirements of the current version of this specification, but it is possible
that a vendor will need to support more complicated filters. In this case, the filter expression syntax can be
extended as follows:

- Additional operators MAY be supported by extending the supported XPath 1.0 subset.
- All extensions MUST use XPath 1.0 lexical rules, operator precedence, type conversions etc.
- Vendor-specific function names MUST be namespace-qualified.
- Vendor-specific DUMetadata and EUMetadata MUST start with X_.
- Vendors MUST make sure that there is no conflict between DUMetadata and EUMetadata.
- Vendor-specific namespaces MUST be declared using the usual XML mechanisms.
- Vendor-specific functions SHOULD be defined only where no standard XPath 1.0 function
  provides a reasonable alternative. This is to maximize the chance that a control point will be able
to parse and understand such a vendor extension.

For example, a vendor who needed a filter to be able to reference more than one argument, check for
argument values beginning with a specified substring, check for DU metadata and call a vendor-specific
function might support the following ACL:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<ACL xmlns="urn:schemas-upnp-org:dm:sms"
     xmlns:ex="http://www.example.com/upnp-dm-sms">
  ...
  <ACLEntry>
    <Action>X_Example_Clean</Action>
    <Filter>ex:urlSchemeIs(DownloadURL,"https") and
     M_DUVersion=1.0</Filter>
    <Roles>Public</Roles>
  </ACLEntry>
</ACL>
```

Copyright UPnP Forum © 2012. All rights reserved.
A control point that understood XPath 1.0 expression syntax would be able to parse the filter expression but would have no way of knowing what the `ex:urlSchemaIs()` function did.
### 2.4 Eventing and Moderation

#### Table 2-9: Event Moderation

<sup>1</sup> Determined by N, where Rate = (Event)/(N secs).

<sup>2</sup> (N) * (allowedValueRange Step).
2.5 Actions

The following Sections contain detailed information about these actions, including short descriptions of the actions, the effects of the actions on state variables, and error codes defined by the actions.

Table 2-10 lists actions, their device and control point support requirements, and their recommended Role Lists and Restricted Role Lists. Only the standard DeviceProtection:1 Admin, Basic and Public Roles are mentioned, because the device manufacturer is free to choose how the dm:3PartyAdmin and dm:UserAdmin Roles (defined in [DEVICE]) relate to the Admin and Basic Roles, and it would therefore be impossible to include them in the table.

Section 2.2.7 defined Non-Restrictable and Restrictable actions and pointed out that all Non-Restrictable actions have a Role List of “Public” and an empty Restricted Role List. Table 2-10 explicitly indicates which actions are Non-Restrictable.

Table 2-10: Actions

</tr>
<tr>
<td>Non-standard actions implemented by an UPnP vendor go here.</td>
<td>X</td>
<td>X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1 R = Required, O = Optional, X = Non-standard.

2 The Role List contains Roles that are authorized to invoke the corresponding action in all contexts.

3 The Restricted Role List contains Roles that are authorized to invoke the corresponding action only in certain contexts. See the individual action definitions for details. For Restrictable actions, the device manufacturer can choose different values for the Restricted Role List.

4 This action is Non-Restrictable. For Non-Restrictable actions, the Role List MUST be “Public” and the Restricted Role List MUST be empty, i.e. the device manufacturer can not choose different values for the Role List or for the Restricted Role List.

5 REQUIRED if the Security feature is supported.

2.5.1 **Install()**

The `Install()` action installs a DU. As a result of this action invocation a new OperationID is generated by the device and is returned. As it is an asynchronous action, details on this ongoing operation can be retrieved using the `GetOperationInfo()` action using the returned OperationID.

After successful installation, at least one DUID is generated and is returned to the control point using the DUIDs evented state variable. DUIDs MAY also be polled from the Software Data Model (see Section 6 Software Data Model).

Depending on the targeted EE, the DU MAY reach the Unresolved state. This state corresponds to the successful installation of the DU with some of its dependencies unresolved. So after the successful completion of the install operation, the state of the DU will be either Unresolved or Installed (see Figure 2-4). Also on some EEs a DU MAY pass through a transitory state named Installing (see Figure 2-1).

### 2.5.1.1 Arguments

The input arguments are used as follows:

- **DUURI**: the URI of the DU that needs to be installed. The value MUST NOT be empty.
- **DUType**: the type of the DU provided by the control point as a hint to help in installation process. This is only a hint and need not match the actual DU type.
- **HandleDependencies**: boolean to trigger the dependency handling mechanism

The output arguments are defined as follows:

- **OperationID**: the identifier of the operation linked to the action call.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Direction</th>
<th>relatedStateVariable</th>
</tr>
</thead>
<tbody>
<tr>
<td>DUURI</td>
<td>IN</td>
<td><code>A_ARG_TYPE_URI</code></td>
</tr>
<tr>
<td>DUType</td>
<td>IN</td>
<td><code>A_ARG_TYPE_DUType</code></td>
</tr>
<tr>
<td>HandleDependencies</td>
<td>IN</td>
<td><code>A_ARG_TYPE_Boolean</code></td>
</tr>
</tbody>
</table>
### 2.5.1.2 Device Requirements

As specified by `DeviceProtection:1`, any control point that possesses any of the `Roles` in the action’s `Role List` MUST be permitted to invoke this action regardless of the values of any action input arguments. If the `Security` feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a `Role List` of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the `Roles` in the action’s `Restricted Role List` MUST be permitted to invoke the action:

- The action was invoked over a TLS connection.
- The control point `Identity` is present in the `DeviceProtection:1` ACL.
- The control point possesses a `Role` that authorizes use of the specified value of the `DUType` argument.

During the action execution, after the DU gets downloaded the following additional check is done:

- The control point possesses a `Role` that satisfies the filter criteria (if it exists).

### 2.5.1.3 Dependency on State

None.

### 2.5.1.4 Effect on State

When the `Install()` is called, a new `OperationID` is assigned to the Operation, which will be in the `Requested` state. The action returns with the `OperationID` output argument, and the `OperationID` is added to the `OperationIDs` list.

When the `Parent Device` is able to process the operation, the `OperationState` will be assigned the `InProgress` state.

A DUID is created and a new instance with the `Installing` state MUST be added into the `Software Data Model`, if the data model is supported. If the `HandleDependencies` is "0", only the DU matching the `DUURL` MUST be targeted by the operation. If it is set to "1" and the device can handle dependencies, then all the dependent DUs also MUST be targeted by this operation. Each of the targeted DUs will be assigned a new `DUID`. As a side effect of the installation of a DU, a new DU instance sub-tree MAY be created for the DU in the `Software Data Model` with the DU state as `Installing`. The sub-tree MUST store information such as the URI of the DU. If any EU is associated to the DU, its corresponding sub-tree MUST also be created.

The operation is considered finished when all the targeted DUs are effectively installed or if any of installation fails. Only when the operation is successful, all the targeted DUs are assigned the `Installed` or `Unresolved` state. At this point the `DUID` of each `Installed` or `Unresolved` DU is added to the `DUIDs` list. Each related EU appears with the `Inactive` state. The IDs of these EUs are added to the `EUIDs` list. Finally, the `OperationID` is removed from the `OperationIDs` list in the `Completed` state. Only one event message SHOULD be sent with the value of the three involved lists.

If the operation fails, all previously successfully installed DUs, i.e., DU in `Unresolved` or `Installed` state, remain in their state. The `OperationID` is removed from the `OperationIDs` list. The operation state is set to `Error` (see 2.3.14).

---

**Argument** | **Direction** | **relatedStateVariable**
--- | --- | ---
`OperationID` | `OUT` | `A_ARG_TYPE_ID`
For some DUs, once the operation is *Completed* a reboot could be necessary. If the \texttt{BMS::SequenceMode} value is set to "1", the reboot SHOULD be avoided until \texttt{BMS::SequenceMode} value is set to "0".

### 2.5.1.5 Errors

**Table 2-12: Error Codes for \texttt{Install()}**

<table>
<thead>
<tr>
<th>errorCode</th>

</tr>
<tr>
<td>704</td>
<td>Already in a transitory state</td>
<td>The action failed because the software entity is already in a transitory state.</td>
</tr>
</tbody>
</table>

### 2.5.2 \texttt{Update()}

The \texttt{Update()} action updates a DU that was already installed and is either in \texttt{Unresolved} or \texttt{Installed} state. As a result of this action invocation a new \texttt{OperationID} is generated by the device and is returned. As it is an asynchronous action, details on the ongoing operation can be retrieved using the \texttt{GetOperationInfo()} action and the \texttt{OperationID}.

The action takes an optional URI input argument from which to update this particular DU. Here optional means that the value MAY be empty. If the \texttt{NewDUURI} is an empty string then the URI used during installation time or during the last successful update, will be used.

On successful update the DUID MUST NOT change and hence the old DUID is still maintained. The state of the DU may be either \texttt{Installed} or \texttt{Unresolved}.

#### 2.5.2.1 Arguments

The input arguments are used as follows:

- **\texttt{DUID}**: the identifier of the DU that needs to be updated.
- **\texttt{NewDUURI}**: the URI of the DU that needs to be used to update the DU instead of the one used for the initial installation or the previous update. The value can be empty.
- **\texttt{HandleDependencies}**: boolean to trigger the dependency handling mechanism of the EE.

Copyright UPnP Forum © 2012. All rights reserved.
The output argument is defined as follows:
- **OperationID**: the identifier of the Operation linked to the action call.

</tbody>
</table>

#### 2.5.2.2 Device Requirements

As specified by **DeviceProtection:1**, any control point that possesses any of the **Roles** in the action’s **Role List** MUST be permitted to invoke this action regardless of the values of any action input arguments. If the **Security** feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a **Role List** of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the **Roles** in the action’s **Restricted Role List** MUST be permitted to invoke the action:
- The action was invoked over a TLS connection.
- The control point **Identity** is present in the **DeviceProtection:1** ACL.
- The control point possesses a **Role** that authorizes this action on DU with specified DUID.

#### 2.5.2.3 Dependency on State

The DU with given **DUID** MUST exist and be assigned the **Installed** or the **Unresolved** state.

#### 2.5.2.4 Effect on State

A new **OperationID** is assigned to the Operation, which will be in the **Requested** state. The action returns with the **OperationID** output argument and the OperationID is also added to the **OperationIDs** list.

If **HandleDependencies** is set to "0", only the DU matching the **DUID** is targeted by the operation. If it is set to "1", and the device can handle dependencies then, all the dependent DUs also must be targeted by this operation. The details of how a device decides which dependent DUs to be targeted for updating is implementation dependent.

A new URI MAY be given as the **NewDUURI** input argument. In that case, the DU is updated from this location. If the argument is set with an empty string, the device updates the DU from a location that is already known by the device, e.g., the URI argument provided to **Install()** action.

The operation is considered **Completed** when:
- all the related EUs which were running are effectively stopped
- all the targeted DUs are effectively updated, i.e., updated, installed or uninstalled
- all the related EUs which were **Active** have been requested to start.

The operation is considered in **Error** state when:
- any of the conditions to reach the **Completed** state is not satisfied.

Copyright UPnP Forum © 2012. All rights reserved.
Final stable state reached by the Parent Device MUST reflect the following:

- all the targeted DUs are assigned the appropriate installed or Uninstalled state,
- new DUIDs, if any, are added to the DUIDs list,
- new EUs, if any, appear in the Inactive state (A control point expects all the EUs to be in their same state as before the update, but in certain circumstances because of for eg: security issues or because of EE behavior the previously running EUs may not be running),
- the IDs of the new EUs are added to the EUIDs list,
- the IDs of the EUs that were successfully started are added to the RunningEUIDs list,
- uninstalled DUIDs, if any, are removed from the DUIDs list,
- EUIDs related to any uninstalled DUs are removed from the EUIDs, the ActiveEUIDs and the RunningEUIDs lists,
- the value of the URI Parameter available in the Software Data Model MUST be updated with the value of the NewDUURI argument if it was specified, i.e., not empty and if the software data model is supported.
- the OperationID is removed from the OperationIDs list in the Completed or Error state.
- only one event message SHOULD be sent with the value of the five involved lists.

If HandleDependencies is set to "0" or if no new DU is installed or removed, the DUIDs list is not modified which means no install or uninstall of DUs.

For some DUs, once the operation is Completed a reboot could be needed. If the BMS::SequenceMode value is set to "1", the reboot SHOULD be avoided until BMS::SequenceMode value is set to "0".

As a side effect of this action the SMS data model MAY need to be updated. If so, this update MUST be done before any of the related state variables are updated.

2.5.2.5 Errors

<td>The \textit{Update()} action failed because the DUID argument is not valid.</td>
</tr>
<tr>
<td>710</td>
<td>NewDUURI not supported</td>
<td>The update() action failed because the NewDUURI is not supported by the EE.</td>
</tr>
</tbody>
</table>

### 2.5.3 \texttt{Uninstall()}

The \texttt{Uninstall()} action uninstalls any DU that is already installed. As a result of this action invocation a new \texttt{OperationID} is generated by the device and is returned. As it is an asynchronous action, details on the ongoing operation can be retrieved using the \texttt{GetOperationInfo()} action and the \texttt{OperationID}.

Upon successful uninstall the state of the DU becomes \textit{Uninstalled}. This state of the DU MAY be maintained in the device for an implementation-specific amount of time to enable a control point to read this state. After a while, the DUID MAY be removed and become invalid.

#### 2.5.3.1 Arguments

The input arguments are used as follows:

- \texttt{DUID}: the identifier of the DU that needs to be uninstalled.
- \texttt{HandleDependencies}: boolean to trigger the dependency handling mechanism of the EE.

The output argument is defined as follows:

- \texttt{OperationID}: the identifier of the operation linked to the action call.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Direction</th>
<th>relatedStateVariable</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{DUID}</td>
<td>IN</td>
<td>\texttt{A_ARG_TYPE_ID}</td>
</tr>
<tr>
<td>\texttt{HandleDependencies}</td>
<td>IN</td>
<td>\texttt{A_ARG_TYPE_Boolean}</td>
</tr>
<tr>
<td>\texttt{OperationID}</td>
<td>OUT</td>
<td>\texttt{A_ARG_TYPE_ID}</td>
</tr>
</tbody>
</table>

### 2.5.3.2 Device Requirements

As specified by \texttt{DeviceProtection:1}, any control point that possesses any of the \texttt{Roles} in the action’s \texttt{Role List} MUST be permitted to invoke this action regardless of the values of any action input arguments. If the \texttt{Security} feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a \texttt{Role List} of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the \texttt{Roles} in the action’s \texttt{Restricted Role List} MUST be permitted to invoke the action:

- The action was invoked over a TLS connection.
- The control point \texttt{Identity} is present in the \texttt{DeviceProtection:1} ACL.
- The control point possesses a \texttt{Role} that authorizes this action on DU with specified DUID.
- The control point installed this DU.

Copyright UPnP Forum © 2012. All rights reserved.
2.5.3.3 Dependency on State
The given DUID MUST exist and identify a DU in the Installed or the Unresolved state.

2.5.3.4 Effect on State
A new OperationID is assigned to the Operation, which will be in the Requested state. The action returns with the OperationID output argument and the OperationID is also added to the OperationIDs list.

If the HandleDependencies is set to "0", only the DU matching the DUID is targeted by the operation. If it is set to "1", and the device can handle dependencies then, all the dependent DUs also must be targeted by this operation. The details of how a device decides which dependent DUs to be targeted for uninstalling is implementation dependent. Each of the targeted DUs is assigned the Uninstalling state. Running EUs which are related to the targeted DUs are assigned the Stopping state.

The operation is considered Completed when:
- all the targeted EUs which were Running are stopped,
- all the targeted DUs are effectively uninstalled

The operation is considered Error when:
- one of the conditions to reach the Completed state is not satisfied.

The DUID of each Uninstalled DU is removed from the DUIDs list. Related EUs are removed from the EUIDs, ActiveEUIDs, and RunningEUIDs lists. Finally, the OperationID is removed from the OperationIDs list in the Completed or Error state. Only one event message SHOULD be sent with the value of all involved lists.

For some DUs, once the operation is Completed a reboot could be needed. If the BMS::SequenceMode value is set to "1", the reboot SHOULD be avoided until BMS::SequenceMode value is set to 0.

As a side effect of this action the SMS data model MAY be updated. If so, this update MUST be done before any of the above mentioned state variables are updated.

2.5.3.5 Errors

</tr>
</tbody>
</table>

### 2.5.4 Start()

The Start() action starts an EU. As it is an asynchronous action, details on the ongoing operation can be retrieved using the GetOperationInfo() action and the OperationID.

When a DU is installed a set of EUs will appear in Inactive state. By invoking a Start() action on these EUs, a control point makes them Active, i.e., asks the EUs to be started. Hence started EUs will be observed as Running.

#### 2.5.4.1 Arguments

The input arguments are used as follows:
- **EUID**: the identifier of the EU to be started.
- **HandleDependencies**: boolean to trigger the dependency handling mechanism of the EE.

The output argument is defined as follows:
- **OperationID**: the identifier of the operation linked to the action call.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Direction</th>
<th>relatedStateVariable</th>
</tr>
</thead>
<tbody>
<tr>
<td>EUID</td>
<td>IN</td>
<td>A_ARG_TYPE_ID</td>
</tr>
<tr>
<td>HandleDependencies</td>
<td>IN</td>
<td>A_ARG_TYPE_Boolean</td>
</tr>
<tr>
<td>OperationID</td>
<td>OUT</td>
<td>A_ARG_TYPE_ID</td>
</tr>
</tbody>
</table>

#### 2.5.4.2 Device Requirements

As specified by DeviceProtection:1, any control point that possesses any of the Roles in the action’s Role List MUST be permitted to invoke this action regardless of the values of any action input arguments. If the Security feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a Role List of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the Roles in the action’s Restricted Role List MUST be permitted to invoke the action:
- The action was invoked over a TLS connection.
- The control point Identity is present in the DeviceProtection:1 ACL.
- The control point possesses a Role that authorizes this action on EU with specified EUID.

#### 2.5.4.3 Dependency on State

The given EUID MUST exist.
2.5.4.4 Effect on State

A new `OperationID` is assigned the `Requested` value and enters the `OperationIDs` list. The action returns with the `OperationID` output argument.

When Software Data Model is implemented, this action sets the 
/UPnP/DM/Software/DU/#/EU/#/RequestedState to reflect that an EU is `Active`.

If the `HandleDependencies` is set to "0", only the EU matching the `EUID` is targeted by the operation. If it is set to "1", and the device can handle dependencies then, all the dependent EUs also must be targeted by this operation. The details of how a device decides which dependent EUs to be targeted for starting is implementation dependent. Each of the targeted EUs is assigned the `Active` state.

The operation is considered finished when all the targeted EUs are `Active` and were requested to start. If the operation is successful, all the targeted EUs are observed in the `Running` state.

The `EUID` of each `Active` EU is added to the `ActiveEUIDs` list. The `EUID` of each EU running is added to the `RunningEUIDs` list.

If the operation is successful, the `OperationID` is removed from the `OperationIDs` list in the `Completed` state.

If the operation fails the `OperationID` removed from the `OperationIDs` list in the `Error` state.

Only one event message SHOULD be sent with the value of all involved lists.

For some EUs, once the operation is `Completed` a reboot could be needed. If the `BMS::SequenceMode` value is set to 1, the reboot SHOULD be avoided until `BMS::SequenceMode` value is set to 0.

As a side effect of this action the SMS data model MAY be updated. If so, this update MUST be done before any of the above mentioned state variables are updated.

2.5.4.5 Errors

Table 2-18: Error Codes for `Start()`

<table>
<thead>
<tr>
<th>errorCode</th>
<th>errorDescription</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>400-499</td>
<td>TBD</td>
<td>See UPnP Device Architecture section on Control.</td>
</tr>
<tr>
<td>500-599</td>
<td>TBD</td>
<td>See UPnP Device Architecture section on Control.</td>
</tr>
<tr>
<td>600-699</td>
<td>TBD</td>
<td>See UPnP Device Architecture section on Control.</td>
</tr>
<tr>
<td>606</td>
<td>Action not authorized</td>
<td>The action requested requires authorization and the sender was not authorized.</td>
</tr>
<tr>
<td>702</td>
<td><code>HandleDependencies</code> request not honored</td>
<td>The <code>Start()</code> action failed because <code>HandleDependencies</code> is set to &quot;1&quot; and the device is unable to handle the software entity dependencies or <code>HandleDependencies</code> is set to &quot;0&quot; and the device is handling software entity dependencies.</td>
</tr>
<tr>
<td>704</td>
<td>Already in a transitory state</td>
<td>The action failed because the software entity is already in a transitory state.</td>
</tr>
<tr>
<td>706</td>
<td>Invalid EUID</td>
<td>The <code>Start()</code> action failed because the <code>EUID</code> argument is not valid.</td>
</tr>
<tr>
<td>709</td>
<td>DU is unresolved</td>
<td>The <code>Start()</code> action failed because the DU related to this EU is still <code>Unresolved</code>.</td>
</tr>
</tbody>
</table>
2.5.5 **Stop()**

The `Stop()` action stops an EU that was already running. As it is an asynchronous action, details on the ongoing operation can be retrieved using the `GetOperationInfo()` action and the OperationID.

By invoking the stop action, the state of an Active EU will be changed to Inactive, i.e., asked to be stopped. Hence the EUID of all the EUs successfully Stopped will leave the RunningEUIDs list.

### 2.5.5.1 Arguments

The input arguments are used as follows:
- **EUID**: the identifier of the EU to be stopped.
- **HandleDependencies**: boolean to trigger the dependency handling mechanism of the EE.

The output argument is defined as follows:
- **OperationID**: the identifier of the operation linked to the action call.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Direction</th>
<th>relatedStateVariable</th>
</tr>
</thead>
<tbody>
<tr>
<td>EUID</td>
<td>IN</td>
<td>A_ARG_TYPE_ID</td>
</tr>
<tr>
<td>HandleDependencies</td>
<td>IN</td>
<td>A_ARG_TYPE_Boolean</td>
</tr>
<tr>
<td>OperationID</td>
<td>OUT</td>
<td>A_ARG_TYPE_ID</td>
</tr>
</tbody>
</table>

### 2.5.5.2 Device Requirements

As specified by `DeviceProtection:1`, any control point that possesses any of the Roles in the action’s Role List MUST be permitted to invoke this action regardless of the values of any action input arguments. If the Security feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a Role List of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the Roles in the action’s Restricted Role List MUST be permitted to invoke the action:

- The action was invoked over a TLS connection.
- The control point Identity is present in the `DeviceProtection:1` ACL.
- The control point possesses a Role that authorizes this action on EU with specified EUID.
- The control point started this EU.

### 2.5.5.3 Dependency on State

The given EUID MUST exist.

### 2.5.5.4 Effect on State

A new OperationID is assigned the Requested value and enters the OperationIDs list. The action returns with the OperationID output argument.
When Software Data Model is implemented, this action sets the
/UPnP/DM/Software/DU/#/EU/#/RequestedState to reflect that an EU is Inactive.

If the HandleDependencies is set to "0", only the EU matching the EUID is targeted by the operation. If it is set to "1", and the device can handle dependencies then, all the dependent EUs also must be targeted by this operation. The details of how a device decides which dependent EUs to be targeted for stopping is implementation dependent. Each of the targeted EUs is assigned the Inactive state.

The action is considered finished when all the targeted EUs are Inactive and were requested to stop.

If the operation is successful, all the targeted EUs are assigned the Inactive state and cease to be running. The EUID of each Inactive EU is removed from the ActiveEUIDs list. The EUID of each Stopped EU is removed from the RunningEUIDs list. Finally, the OperationID is removed from the OperationIDs list in the Completed or Error state. Only one event message SHOULD be sent with the value of all involved lists.

For some EUs once the operation is Completed a reboot could be needed. If the BMS::SequenceMode value is set to 1, the reboot SHOULD be avoided until BMS::SequenceMode value is set to 0.

As a side effect of this action the SMS data model MAY be updated. If so, this update MUST be done before any of the related state variables are updated.

### 2.5.10  **GetOperationInfo()**

The **GetOperationInfo()** action gets the information about an operation identified by an **OperationID**.

Copyright UPnP Forum © 2012. All rights reserved.
Once an operation has been successfully requested, the operation info SHOULD remain available at least
until a disappearance / reappearance of the SoftwareManagement service on the network, e.g., as a result of
a power cycle. An implementation MAY drop the oldest OperationIDs from the list because of memory
constraint. An implementation MAY retain operation info across a service restart.

2.5.10.1 Arguments
The input argument is used as follows:
- OperationID: the identifier of the targeted operation.

The output arguments are defined as follows:
- OperationState: the state of the operation.
- TargetedIDs: the IDs of the DUs or the EUs targeted by the operation. The first ID MUST
  identify the software entity explicitly targeted by the operation, e.g., the EUID passed in to the
  Start() action. If the operation state is Requested, InProgress or Error the TargetedIDs list MAY
  be incomplete and possibly empty. When the operation is Completed, the list MUST be
  exhaustive.
- Action: the action that has initiated the operation.
- ErrorDescription: detailed description of error state. In case of completion without error,
  Error_None MUST be returned.
- AdditionalInfo: an informative description of the result of the operation.

Table 2-29: Arguments for GetOperationInfo()

<table>
<thead>

</tr>
</tbody>
</table>

2.5.10.2 Device Requirements
This action is Non-Restrictable and all control points MUST be permitted to invoke the action regardless of
which Roles they possess.

2.5.10.3 Dependency on State
The given OperationID MUST exist.

2.5.10.4 Effect on State
None.

2.5.10.5 Errors

Table 2-30: Error Codes for GetOperationInfo()
2.5.11 GetOperationIDs()

The GetOperationIDs() action returns the current value of the OperationIDs state variable.

2.5.11.1 Arguments

The output argument is defined as follows:

- **OperationIDs**: the identifiers of all the on going Operations i.e., Operations in either Requested or InProgress state.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Direction</th>
<th>relatedStateVariable</th>
</tr>
</thead>
<tbody>
<tr>
<td>OperationIDs</td>
<td>OUT</td>
<td>OperationIDs</td>
</tr>
</tbody>
</table>

2.5.11.2 Device Requirements

This action returns the value of an evented state variable. This value is freely available to all control points, so the Parent Device MUST permit all control points to invoke the action regardless of which Roles they possess.

2.5.11.3 Dependency on State

None.

2.5.11.4 Effect on State

None.

2.5.11.5 Errors

</tbody>
</table>

2.5.13 **GetDUIInfo()**
The *GetDUIInfo()* action gets the information about a DU identified by its DUID.

Information about a DU MUST be available as soon as the DU is Installed. Information about the DU is removed as soon as the DU is Uninstalled.
2.5.13.1 Arguments
The input argument is used as follows:
- **DUID**: the identifier of the DU.

The output arguments are defined as follows:
- **DUName**: the name of the DU.
- **DUVersion**: the version of the DU.
- **DUType**: the type of the DU.
- **DUSate**: the state of the DU.
- **DUURI**: the URI of the DU from where it is installed or updated. The value MUST NOT be empty.

</tr>
</tbody>
</table>

2.5.13.2 Device Requirements
As specified by **DeviceProtection:1**, any control point that possesses any of the **Roles** in the action’s **Role List** MUST be permitted to invoke this action regardless of the values of any action input arguments. If the **Security** feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a **Role List** of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the **Roles** in the action’s **Restricted Role List** MUST be permitted to invoke the action:

- The action was invoked over a TLS connection.
- The control point **Identity** is present in the **DeviceProtection:1** ACL.
- The control point possesses a **Role** that authorizes this action on DU with specified DUID.

2.5.13.3 Dependency on State
The given **DUID** MUST exist.

2.5.13.4 Effect on State
None.

2.5.13.5 Errors

Table 2-36: Error Codes for **GetDUInfo()**
<table>
<thead>
<tr>

</tr>
</tbody>
</table>

2.5.14 GetEUInfo()

The GetEUInfo() action gets the information about an EU identified by its EUID.

Information about an EU MUST be available as soon as the related DU is installed successfully because EUs appear on successful installation of DUs. Information about the EU will be removed as soon as the corresponding DU is uninstalled.

2.5.14.1 Arguments

The input argument is used as follows:
- **EUID**: the identifier of the EU.

The output arguments are defined as follows:
- **EUName**: the name of the EU.
- **EUVersion**: the version of the EU.
- **EURequestedState**: the requested state of the EU.
- **EURunningState**: the running state of the EU.

<table>
<thead>
<tr>
<th>Argument</th>

<td>A_ARG_TYPE_EURunningState</td>
</tr>
</tbody>
</table>

2.5.14.2 Device Requirements

As specified by DeviceProtection:1, any control point that possesses any of the Roles in the action’s Role List MUST be permitted to invoke this action regardless of the values of any action input arguments. If the Security feature is not supported, all actions are permitted, i.e. behavior is the same as if the action had a Role List of “Public”.

Otherwise, if all of the following conditions are met, any control point that possesses any of the Roles in the action’s Restricted Role List MUST be permitted to invoke the action:

Copyright UPnP Forum © 2012. All rights reserved.
• The action was invoked over a TLS connection.
• The control point Identity is present in the DeviceProtection:1 ACL.
• The control point possesses a Role that authorizes this action on EU with specified EUID.

2.5.14.3 Dependency on State
The given EUID MUST exist.

2.5.14.4 Effect on State
None.

2.5.14.5 Errors

<td>(Specified by UPnP vendor.)</td>
</tr>
</tbody>
</table>
2.6 Theory of Operation

This informative section explains various scenarios to illustrate the actions that are supported by SoftwareManagement Service. The SoftwareManagement Service will support the following actions: Install(), Update(), Uninstall(), Start() and Stop() on software entities.

2.6.1 Scenarios

2.6.1.1 Dependency Handling

Dependency handling means one software entity being dependent on another software entity. For example a DU may be dependent on other DUs and an EU may be dependent on other EUs. Dependency handling is a capability of the EE. For example, an OSGi EE is able to handle dependencies. The properties 
/UPnP/DM/Software/Capabilities/AbleToHandleUDependency and 
/UPnP/DM/Software/Capabilities/AbleToHandleEUDependency are used to indicate the capabilities. How SMS handles the dependencies is implementation specific. Below are some possible outcomes (Note: first DU is the DU on which the action is invoked):

1) During installation of a first DU, dependency handling may install other DUs as well. If dependent DUs are not installed, the first DU will be in Unresolved state else it will be in Installed state.

2) During update of a first DU, dependency handling may uninstall some DUs which are not in use currently and were installed because of dependency during installation and install some more new DUs. The running EUs corresponding to the updated DUs are stopped and restarted.

3) During uninstall of a first DU, dependency handling may uninstall some DUs which are not in use currently and were installed because of dependency during installation of first DU. EUs corresponding to the uninstalled DUs are stopped.

4) During start of a first EU, dependency handling may start some EUs on which the first EU is dependent upon.

5) During stop of a first EU, dependency handling may stop some EUs which are not in use currently and were started because of dependency handling during start of first EU.

2.6.1.2 Installing a Software entity successfully

The Install() action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.1.2).

1. Without dependency

A control point invokes the install() action giving the URI of a first DU to be installed on to an EE. A URI is most probably a URL for practical purposes. After receiving the install action, the Parent Device will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. Once the operation is successfully executed, the first DU appears in Installed state (assuming no dependency). A new DUID is assigned to this DU, data model MAY be updated and this is added to the DUIDs state variable. All the EUs associated to this first DU appear in the Inactive state and their IDs are added to EUIDs state.

Copyright UPnP Forum © 2012. All rights reserved.
variable. The operation is successful and the *OperationID* is removed from the *OperationIDs* list. All the state variables are evented in a single event.

![Diagram](image)

**Figure 2-5 Installing a software entity successfully without dependency**

2. **With Dependency**

A control point invokes the install action giving the URI of a first DU to be installed on to an EE along with dependency handling. With dependency handling on successful completion of an install operation all dependent DUs will be either installed or unresolved in addition to the first DU which will also be either in the installed or unresolved state. All EUs corresponding to the DUs will appear in the **Inactive** state. Other flow remains the same as above.

2.6.1.3 **Installing a software entity (failure case)**

The *Install()* action is required. Its *Role List* is “Admin” and Restricted *Role List* is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.1.2).

A control point invokes the install action giving the URI of a first DU to be installed on to an EE along with dependency handling. If an *Error* occurs because of a dependent DU, the installation proceeds with other DUs without effecting the operation. But if an *Error* occurs because of the first DU and some of its
dependent DUs are already installed, in that case implementations may choose to rollback and hence uninstall the dependent DUs installed in this operation. Note that the order of installation of DUs is implementation dependent. In any case control points depend on the evented state variables DUIDs, EUIDs, ActiveEUIDs and OperationIDs. Even in the failure case these state variables will be updated and control points will be in sync with the Parent Device.

2.6.1.4 Update a Software entity successfully

The Update() action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.2.2).

A software entity can be a piece of software or firmware represented as a DU. For update a firmware is treated as a special kind of software. A firmware can be envisioned in terms of DU and EU. The primary firmware is identified using the ID “0” for both DUID and EUID. So updating a primary firmware is done by calling the Update() action on DUID “0”.

Treating firmware as a common software entity gives the flexibility of designing a monolithic firmware as well as a modular firmware. An implementation is free to choose a set of DUs and EUs as firmwares. In any case DUID and EUID “0” are reserved for the primary firmware, i.e., the firmware the physical device is booting on.

Below are two scenarios with dependency and without dependency for updating a software entity.

1. Without Dependency

A control point invokes the Update() action by optionally giving the new URI from where to update an already installed/ unresolved DU on to an EE. After receiving the Update() action, the SMS will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. The already installed or unresolved DU will be uninstalled and a new DU will be installed from the new location or from a previously stored location. The previous DUID is retained. After a successful update the DU can be either unresolved or installed. Any related EUs which are running will be stopped. After update of a DU all the related EUs will appear in Inactive state irrespective of their previous state. These EUs will be treated as new EUs and are having new EUIDs. The OperationID is removed from the OperationIDs list. The data model MAY be updated and the related state variables are updated for eventing.

2. With Dependency

A control point invokes the Update() action optionally giving the new URI from where to update an already installed/unresolved DU on to an EE along with dependency handling. After receiving the Update() action, the SMS will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. The already installed or unresolved DU will be uninstalled and a new DU will be installed from the new location or from a previously stored location. The previous DUID is retained. The same is repeated for all dependent DUs. With dependency handling, on successful completion of an update operation, all dependent DUs will be either installed or unresolved in addition to the first DU which will also be either in the installed or unresolved state. All the related EUs which are running will be stopped. After update all the related EUs will appear in Inactive state irrespective of their previous state. These EUs will be treated as new EUs and are having new EUIDs. The OperationID is removed from the OperationIDs list. The data model MAY be updated and the related state variables are updated for eventing.
2.6.1.5 Updating a software entity (failure case)
The `Update()` action is required. Its `Role List` is “*Admin*” and `Restricted Role List` is “*Public, Basic*”. This means that control points that possess “*Admin*” role are permitted to invoke this action unrestrictively. Also control points which possess “*Public*” or “*Basic*” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.2.2).

A control point invokes the `Update()` action by optionally giving the new URI from where to update an already installed/unresolved DU on to an EE along with dependency handling. If during update an `Error` occurs because of a dependent DU, the update proceeds with other DUs without effecting the operation. But if an `Error` occurs because of the first DU and some of its dependent DUs are already updated, in that case implementations may choose to rollback and hence uninstall those dependent DUs installed in this operation. Note that the order of installation of DUs is implementation dependent. In any case control points depend on the evented state variables `DUIDs, EUIDs, ActiveEUIDs` and `OperationIDs`. Even in the failure case these state variables will be updated and control points will be in sync with the `Parent Device`.

2.6.1.6 Uninstall a Software entity successfully
The `Uninstall()` action is required. Its `Role List` is “*Admin*” and `Restricted Role List` is “*Public, Basic*”. This means that control points that possess “*Admin*” role are permitted to invoke this action unrestrictively. Also control points which possess “*Public*” or “*Basic*” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.3.2).

1. Without Dependency
A control point invokes the `Uninstall()` action giving the `DUID` of a DU to be uninstalled from an EE. After receiving the `Uninstall()` action, the `Parent Device` will create an operation and return the `OperationID`. This `OperationID` is added to the `OperationIDs` state variable and is evented. The operation is successfully completed once the DU corresponding to the `DUID` is uninstalled and that DU is removed from the `DUIDs` list. The EUs corresponding to the DU are stopped and removed from the `EUIDs` and `RunningEUIDs` list. The data model MAY be updated and `OperationID` is removed from `OperationIDs` list. All the state variables are evented.

2. With Dependency
A control point invokes the `Uninstall()` action giving the `DUID` of a first DU to be uninstalled from an EE along with dependency handling. After receiving the `Uninstall()` action, the `Parent Device` will create an operation and return the `OperationID`. This `OperationID` is added to the `OperationIDs` state variable and is evented. The operation is successfully completed once all the DUs which are installed because of dependency handling will be uninstalled along with the first DU. A dependent DU will be uninstalled if and only if no more dependencies exist on it. All DUs are removed from the `DUIDs` list. All the EUs corresponding to the DUs are stopped and removed from the `EUIDs` and `RunningEUIDs` list. The `OperationID` is removed from `OperationIDs` list. The data model MAY be updated and state variables are evented.

2.6.1.7 Uninstall a software entity (failure case)
The `Update()` action is required. Its `Role List` is “*Admin*” and `Restricted Role List` is “*Public, Basic*”. This means that control points that possess “*Admin*” role are permitted to invoke this action unrestrictively. Also control points which possess “*Public*” or “*Basic*” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.3.2).

A control point invokes the `Uninstall()` action giving the `DUID` of a first DU to be uninstalled from an EE along with dependency handling. After receiving the uninstall action, the `Parent Device` will create an operation and return the `OperationID`. This `OperationID` is added to the `OperationIDs` state variable and is evented. If during uninstall an `Error` occurs because of a dependent DU, the uninstall proceeds with other
DUs without effecting the operation. But if an Error occurs because of the first DU and some of its dependent DUs are already uninstalled, in that case implementations may choose to rollback and hence install those dependent DUs uninstalled in this operation. Note that the order of uninstall of DUs is implementation dependent. In any case control points depend on the evented state variables DUIDs, EUIDs and OperationIDs. Even in the failure case these state variables will be updated and control points will be in sync with the Parent Device.

2.6.1.8 Start a Software entity successfully
The Start () action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.4.2).

1. Without Dependency
A control point invokes the Start() action giving the EUID of an EU to be started on an EE. After receiving the Start() action, the Parent Device will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. The operation is successfully completed once the EU corresponding to the EUID is started. The EUID is then added to the ActiveEUIDs list and the RunningEUIDs list if observed as running. The OperationID is removed from OperationIDs list. The data model MAY be updated and state variables are evented.

2. With Dependency
A control point invokes the Start() action giving the EUID of an EU to be started on an EE along with dependency handling. After receiving the Start() action, the Parent Device will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. The operation is successfully completed once the EU corresponding to the EUID and its dependent EUs are started. The EUIDs are added to the ActiveEUIDs and RunningEUIDs list if observed as running. The OperationID is removed from OperationIDs list. The data model MAY be updated and state variables are evented.

2.6.1.9 Start a Software entity (failure case)
The Start () action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.4.2).

A control point invokes the Start() action giving the EUID of a first EU to be started on an EE along with dependency handling. After receiving the Start() action, the Parent Device will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. If during start an Error occurs because of a dependent EU, the start proceeds with other EUs without effecting the operation. But if an Error occurs because of the first EU and some of its dependent EUs are already started, in that case implementations may choose to rollback and hence stop those dependent EUs started in this operation. Note that the order of start of EUs is implementation dependent. The EUID is added to the ErrorEUIDs list. In any case control points depend on the evented state variables EUIDs, ActiveEUIDs, RunningEUIDs, ErrorEUIDs and OperationIDs. Even in the failure case these state variables will be updated and control points will be in sync with the Parent Device.
2.6.1.10  Stop a Software entity successfully
The Stop() action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.5.2).

1.  Without Dependency
A control point invokes the Stop() action giving the EUID of an EU to be stopped on an EE. After receiving the Stop() action, the Parent Device will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. The operation is successfully completed once the EU corresponding to the EUID is stopped. The EUID is then removed from the ActiveEUIDs list and the RunningEUIDs list if observed as no more running. The OperationID is removed from OperationIDs list. The data model MAY be updated and state variables are evented.

2.  With Dependency
A control point invokes the Stop() action giving the EUID of an EU to be stopped on an EE along with dependency handling. After receiving the Stop() action, the Parent Device will create an operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. The operation is successfully completed once the EU corresponding to the EUID along with its dependent EUs are stopped. A dependent EU will be stopped if and only if no more dependencies exist on it. The EUIDs are then removed from the ActiveEUIDs list and the RunningEUIDs list if they are no more observed as running. The OperationID is removed from OperationIDs list. The data model MAY be updated and state variables are evented.

2.6.1.11  Stop a Software entity (failure case)
The Stop() action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.5.2).

A control point invokes the Stop() action giving the EUID of a first EU to be stopped on an EE along with dependency handling. After receiving the stop action, the Parent Device will create an Operation and return the OperationID. This OperationID is added to the OperationIDs state variable and is evented. If during stop an Error occurs because of a dependent EU, the stop proceeds with other EUs without effecting the operation. But if an Error occurs because of the first EU and some of its dependent EUs are already stopped, in that case implementations may choose to rollback and hence start those dependent EUs stopped in this operation. Note that the order of stop of EUs is implementation dependent. The EUID is added to the ErrorEUIDs list. In any case control points depend on the evented state variables EUIDs, ActiveEUIDs, RunningEUIDs, ErrorEUIDs and OperationIDs. Even in the failure case these state variables will be updated and control points will be in sync with the Parent Device.

2.6.1.12  Firmware update
The Update() action is required. Its Role List is “Admin” and Restricted Role List is “Public, Basic”. This means that control points that possess “Admin” role are permitted to invoke this action unrestrictively. Also control points which possess “Public” or “Basic” role are permitted to invoke this action if they satisfy other criteria as mentioned in the action description (Section 2.5.2.2).

Firmware is envisioned to be a modular firmware in the context of Software Management. There are two kinds of firmware; one is the primary firmware (identified using the DUID 0 and EUID 0) and another is a normal firmware treated as any other software. The update of primary firmware is same as updating the
operating system itself. The Firmware update is performed using the same `Update()` action which is used for software update. There are two scenarios here; one is update of primary firmware and another is update of normal firmware.

1. **Update of Primary Firmware**

   A firmware with **DUID 0** is already installed in the device. The corresponding EU with **EUID 0** is already active. To update this primary firmware a control point will invoke `Update(0, NewDUURI, 0)`. The following steps take place on this action invocation (see Figure 2-6):

   1. **DUID 0 and EUID 0** are removed from the **DUIDs** and **EUIDs** list respectively which is then evented. This is an indication to the control point that the primary firmware is getting updated.

   2. EU 0 is stopped
   3. DU 0 is updated
   4. EU 0 is requested to start again

---

**Figure 2-6 Update of Primary Firmware**

**DUID 0** and **EUID 0** are removed from the **DUIDs** and **EUIDs** list respectively which is then evented. This is an indication to the control point that the primary firmware is getting updated.

EU 0 is stopped
DU 0 is updated
EU 0 is requested to start again

---

Copyright UPnP Forum © 2012. All rights reserved.
DUID 0 and EUID 0 is again added to the DUIDs and EUIDs list respectively which is then evented. This is an indication to the control point that the primary firmware is successfully updated.

Note: A Primary firmware MUST NOT be dependent on any other DU or EU. Hence HandleDependencies is always 0.

2. Update of Normal Firmware

Normal firmware is treated as any other software and the update procedures that are followed are similar to that of the normal software. See sections 2.6.1.4 and 2.6.1.5.

5 Execution Platform Technologies (Informative)

This section is based on a first study of some execution platform technologies targeting embedded devices: Linux Debian, Microsoft .NET Platform, Java OSGi [OSGi], Java MIDP3 [MIDP]. The ongoing specification work named OMA SCOMO [SCOMO] is also studied. Like this specification, it is also an attempt to standardize a generic protocol to manage the software lifecycle of software execution platforms.

Execution Platform technologies

Most of the execution platform technologies define – at least enable – the deployment and the execution of modular software applications. After the statement of general definitions, the following technologies are described: Linux, Microsoft .NET, OSGi [OSGi], Java MIDP version 2 and 3 [MIDP], SCOMO [SCOMO].

Definitions

The management of the lifecycle of software entities is one Device Management function. The managed entities are of various kinds, e.g., applications, graphical interface items, drivers. Devices that are embedded usually define a software image that is called firmware that can only be upgraded as a whole. Other devices often provide the means to manage more fine-grained software entities that are hosted by an operating system, e.g., Windows, Linux, a modular application, e.g., a browser, or a virtual machine e.g., .NET, Java.

Execution Environment’s usually define the following terms. Table 5-1 compares various software platform technologies:

- **Deployment Unit (DU):** a binary unit that can be individually deployed on the Execution Environment. A deployment unit consists of resources such as library files, functional execution units, and configuration files, i.e. jar files, bundles, assemblies, etc.

- **Execution Unit (EU):** a functional entity that, once started, initiates process to perform tasks or provide services, until that it is stopped. Execution units are deployed by deployment units, i.e. services, scripts, software components, MIDlets, etc.

- **Dependencies:** resource dependencies – e.g., libraries, files – can be defined between deployment units, between execution units and between deployment units and execution units. Execution units appear with the installation of deployment units. They are contained by deployment units – e.g., a .NET assembly and an OSGi bundle are deployment units that contain at most one bootstrap class that can be started, a MIDlet Suite can contain one or more MIDlets that can be started and stopped.

- **Metadata:** data that describe the software entities – vendor, update location, Execution Environment, dependencies, configuration, etc.:
  - Optional general properties
  - Platform-specific properties useful for deployment

- **Software lifecycle management operations**
  - For DU, e.g., install, uninstall, update.
  - For execution units, e.g., start, stop.

- **Software entity states**
  - Of DU, e.g., unresolved, installed, uninstalled.
  - Of execution units, e.g., stopped, started.
• Events: they are usually related to the achievement of management operation and to state changes. Events are distinct from operation responses in that they are asynchronous and are notified to not only the operation initiator but also other managing entities.

• DU repositories: Repositories can be defined by the technology or by management tools. They are sometimes local, e.g., .NET Global Assembly Cache, and sometimes remote, e.g., RedHat RPM repositories, OSGi bundle repository.

• Execution unit repositories: Other repositories enumerate active entities, e.g., OMA SCOMO inventory, or parts of active entities, e.g., Linux process list, OSGi service registry.

Linux Packages

Linux is probably the most widespread Execution Environment on the embedded devices of local networks (e.g., the home network). Linux could have been considered as a de facto standard if derivatives were not as numerous as they are today. Slackware, Debian et Red-Hat define the main families. All the other main distributions are deriving from these ones, e.g., Ubuntu, Mepis, Zenwalk, Mandriva, Suze. The structure and the lifecycle of the software entities defined by these distributions are different from one distribution to the other. However, all the distributions show some common points:

• **Package**: The Package is common to the three Linux families.

• **Execution unit**: the RC script is an entity that is common to several Linux distributions. Init processes can also be considered as execution units.

• **Dependencies**: package dependencies are explicit in some distributions like the one of the Debian family where the package manager is able to install all the packages which a package depends on when the installation of the latter is demanded. No metadata is defined to link the RC script with packages.
• **Metadata**: Processes are not described by any metadata. On the contrary, RedHat and Debian packages show metadata that describe dependencies and general deployment information. Here is the list of Debian package properties:
  o Optional general properties: Package, Version, Section, Installed-Size, Maintainer, Description.
  o Platform-specific properties useful for deployment: Priority, Architecture, Essential, Depends, Pre-Depends, Recommends, Suggests, Conflicts, Replaces, Provides.

• Software lifecycle management operations (see Figure)
  o For DUs: Install, Remove, Upgrade\(^2\).
  o For execution units: Start, Stop. They are the most common operations that can be performed on RC scripts or other init processes.

• Software entity states (see Figure)
  o Of Deployment Units: Installed, Removed, Resolved. Since dependency resolution mechanisms are available on Linux Debian and RedHat platforms, the "Resolved" state is a state that can be displayed for the DUs. Many transitory states are specified but they are not represented here.
  o Of Execution Units: Inactive, Active. RC scripts can be defined whereas useful DUs are not available yet. However, they can only be started when the necessary DUs are installed.

• Events: It is possible to be notified of the activity change of the RC scripts thanks to the process table. POSIX signals are also available for the follow-up of init daemons.

• DU repositories: Debian and RedHat repositories.

• Execution unit repositories: The process table enumerates the running and defunct processes.

![Figure 55-1 A general vision of Linux software entities and their state diagrams](image)

**OSGi bundles**

The OSGi technology defines a modular deployment platform for Java applications. Far from the initial vision of an Internet Gateway at creation time in 1999, a more general objective has been targeted by the

\(^2\) Even if the detailed Debian manual is more sophisticated, the overall set of operations is about installation, update and uninstallation: [http://www.debian.org/doc/debian-policy/ch-maintainerscripts.html#s-mscriptssync](http://www.debian.org/doc/debian-policy/ch-maintainerscripts.html#s-mscriptssync)
OSGi Alliance: "OSGi technology is the dynamic module system for Java" is written on their web site. The technology defines fine-grained code sharing and isolation mechanisms between deployment units called bundles. These mechanisms and a set of good practices make it possible to simultaneously execute applications constituted by several bundles that coexist and share code and loaded objects. Sharing and isolation rules are applied by the platform according to bundle dependencies described in their manifest and security directives.

Here are the characteristics of the bundle lifecycle defined by the OSGi specification release 4 version 4.1 [OSGi]:

- **Deployment Unit**: the OSGi bundle is a JAR file that may contain Java class files, other JAR files, a Manifest file describing bundle metadata, other non-OSGi resources.
- **Execution Unit**: Every OSGi bundle declaring a fine named "Activator" can be started or stopped on the platform. The other bundles are inert resource libraries.
- **Dependencies**: Every OSGi bundle must declare the versioned packages it provides, the ones it requires and the ones that remain private inside the bundle. It may also define dependencies towards bundles. The OSGi platform is responsible for the resolution diagnostic of bundle package dependencies. A non resolved bundle is prevented to start by the platform. Some more sophisticated component model (e.g., OSGi Declarative Services) enable the definition of internal components inside bundles and service dependencies between them.
- **Metadata**: The following properties are defined for OSGi bundles:
  - Optional general properties: Bundle-Category, Bundle-ContactAddress, Bundle-Copyright, Bundle-Description, Bundle-DocURL, Bundle-Localization, Bundle-Name, Bundle-Vendor, Bundle-Version.
- **Software lifecycle management operations** (see Figure 5-2): Every bundle can be installed, uninstalled, updated, started, stopped thanks to the available methods: Install, Uninstall, Update, Start, Stop. However, starting and stopping a bundle that does not declare an "Activator" file have no effect. Despite a "Resolved" state is specially specified, resolution mechanisms can only be triggered by the platform itself (no "Resolve" method is defined).
- **Software entity states** (see Figure 5-2): Installed, Resolved, Uninstalled, Active. The "Resolved" state indicates that the resolution diagnostic has been performed and that required packages (and bundles) are effectively available on the platform. OSGi bundles enter transitory states when start and stop operations are initiated: Starting, Stopping.
- **Events**: "Installed", "Uninstalled", "Updated", "Resolved", "Unresolved", "Starting", "Started", "Stopping", "Stopped". The bundle activity is also visible thanks to the state notification of provided services: "Registered", "Modified" and "Unregistered".
- **Deployment Unit repositories**: The de facto OBR standard (OSGi Bundle Repository) describes a list of stored bundles. This format can be used not only for remote repositories but also for local ones.
- **Execution unit repositories**: Well-known OSGi platforms provide platform administrators with a tool listing the hosted OSGi bundles with their state and metadata. The tool also enables operations on the bundles. Services and their states may also be listed.

Java MIDlets

Java MIDP (Mobile Information Device Profile) defines software entities deployable on a constrained Java virtual machine specified by Java CLDC (Connected Limited Device Configuration). MIDP is known under 3 versions. What is indicated here is true on MIDP2 [MIDP] and on MIDP3. Much more restrictive than the OSGi model, CLDC/MIDP specifies an all-or-nothing mode for code sharing between software entities. This mode follows the "sandbox" model. Inside a MIDlet Suite – the MIDP deployment unit, every part has access to the other parts and to the libraries hosted by the underlying platform. However, no part has access to the code inside other MIDlet Suites. If MIDP3 brings the notion of library (LIBlet) sharing between MIDlet Suites, this follows the sandbox model by preventing the sharing of objects at runtime (the shared library is separately loaded by each requesting MIDlet Suite). Only Inter-Process Communication (IPC) is enabled between MIDlet Suites. Every MIDlet Suite may contain several execution units called MIDlets. The lifecycle of each of these entities is described on Figure 5-3.

Here are the platform characteristics [MIDP]:

- Deployment Unit: a MIDlet Suite is a JAR file containing the code of one or several MIDlets, a JAD (Java Application Descriptor) file describing them and some non-Java resources.
- Execution Unit: MIDlet.
- Dependencies: A MIDlet Suite may contain one or several MIDlets. Before MIDP3, dependencies were defined neither between MIDlets nor between MIDlet Suites. With MIDP3, every MIDlet may provide and require inert libraries.
- Metadata: Metadata is written to the JAD file.
  - Optional general properties: MIDlet-Name, MIDlet-Version, MIDlet-Vendor, MIDlet-Jar-URL, MIDlet-Jar-Size, MIDlet-Description, MIDlet-Icon, MIDlet-Info-URL, MIDlet-Data-Size.
- Software lifecycle management operations (see Figure 5-3)
  - For Deployment Units: Install, Remove, Update.
  - For Execution Units: StartApp, StopApp. The first two versions of MIDP specified a pausing operation (PauseApp). This operation is now deprecated in the 3rd version.
- Software entity states (see Figure 5-3)
  - Of Deployment Units: Installed, Removed.

Copyright UPnP Forum © 2012. All rights reserved.
o Of Execution Units: Destroyed, Active. The "Paused" state is deprecated in MIDP3. MIDlets appear with the "Destroyed" state when the associated MIDlet Suite is installed (see on the right of Figure 5-3).

- Events: Only a global application manager, called JAM (Java Application Manager), is aware of state transition of MIDlets.
- Deployment Unit repositories: It is possible to create a MIDlet Suite repository thanks to the information of MIDlet Suite application descriptors (JAD files).
- Execution unit repositories: MIDP platforms usually provide a tool listing available MIDlets and their state.

![Figure 5-3 The lifecycle of MIDlet Suites and the one of their MIDlets](image)

**.NET Assemblies**

.NET is an Execution Environment specified by Microsoft. The innovation mainly relies in the definition of a virtual machine interpreting a binary code that is common to the compilation of several programming languages (e.g., C#, VB#, J#). .NET is born in the same period as the OSGi standard (see section 0). Some similar characteristics are shared by these technologies: virtual machine, dynamic loading of software entities called "assembly", assembly dependency resolution performed by the underlying platform thanks to assembly metadata. Code sharing and isolation are defined at the type level. Visibility levels called "public" and "internal" distinguish the types that are visible outside the assembly from the types that remain private to the assembly internal code. The public assembly code is visible from the other assemblies hosted by the same Application Domain (AppDomain) whereas the assemblies of distinct Domains can only communicate through the Inter-Process Communication (IPC). An assembly can be dynamically, i.e., at runtime, loaded by one or several domains. However, the assemblies are separately loaded by distinct Domains and one assembly can not be unloaded by a domain without unloading the whole domain. These limits make the .NET modularity appear between the OSGi flexibility and the all-or-nothing mode of the MIDP3 sandbox model.

Here, the .NET platform characteristics are summarized:

- Deployment Unit: An assembly is a set of resources described by a manifest file. It can be dynamically loaded by one or several Application Domains.
- Execution unit: Every activable assembly offers an Entry Point with a generic invocation method, named invoke(), accepting a table of input arguments.
- Dependencies: Every assembly declares public types and the assemblies that it requires.
- Metadata: The following properties can be found in the manifest file of an assembly. For convenience, the "Assembly" prefix of every property name has been removed in the list:

Platform-specific properties useful for deployment: Name, FileList, TypeReference, ReferencedAssemblies, EntryPoint, Configuration, DelaySign, KeyFile, KeyName.

- Software lifecycle management operations (see Figure 5-4): every assembly can be
  - Downloaded and removed in the local repository called "Global Assembly Cache" or in the AppDomain particular caches.
  - Then loaded (Assembly.Load()), invoked (Assembly.EntryPoint.invoke(Object[] optionalParams) or AppDomain.ExecuteAssembly(Assembly a)). Dependency resolution is performed by the underlying platform itself.

- Software entity states (see Figure 5-4): Downloaded, Loaded, Unloaded. No activity state is defined. And although resolution mechanisms are part of the platform, the successful invocation (activation) of an assembly does not prevent the hosting Domain to throw "AssemblyResolve" exceptions when executing it.

- Events: "AssemblyLoad" when an assembly is loaded, "AppDomainUnload" when a Domain is unloaded, "AssemblyResolve" when a required type is missing at the moment of use.

- Deployment Unit repositories: The Global Assembly Cache is a local assembly cache where applications share assemblies. Every Domain has also a private cache.

- Execution unit repositories: The .NET platform is delivered on Windows with some tools like the .Net Framework Configuration, which maintains the list of available assemblies and enables their removal.

**SCOMO Components: a attempt of generalization**

SCOMO [SCOMO] is an ongoing specification of the Open Mobile Alliance. Unlike the previous execution platforms, SCOMO is not a software platform associated to a programming language. It is a protocol, which, linked to OMA DM protocols, enables the software management of software entities of various embedded platforms. It then follows a general approach similar to the one of the specification of the Software Management Service in the UPnP Device Management Working Committee, i.e., the definition of a generic protocol for the management of any software platform technology. SCOMO Delivery Package and Deployment Component both part of the DU concept while SCOMO Software Component matches the EU concept of this specification.

Here are the "platform" characteristics:

Copyright UPnP Forum © 2012. All rights reserved.
• Deployment Unit: The concept is specified into two separate entities: the SCOMO Delivery Package (DP) and the SCOMO Deployment Component (DC). After a DP is downloaded, the set up of it installs the contained DCs. The removal of a DP does not involve the removal of the related DCs. A DC can be explicitly removed by a command. Activation and Deactivation of a DC are defined but these operations are not similar to the activation and deactivation of an EU in this specification. Indeed, the active DCs are not running. The activation only makes "services or resources it embodies accessible to other entities or resources (including end-user)" so that "a service that consists of multiple Deployment Components is ready for launch after all the relevant Deployment Components have reached the Active state" (see [SCOMO])³.

• Execution Unit: The concept is reified into SCOMO Software Component (SC). However, SCOMO does not define any operation on SCs and leaves the launch of "services" to terminal-specific interactions.

• Dependencies: A DP may contain one or several DCs. A DC contains a Software Component and related metadata.

• Metadata: Every entity is defined with metadata that are described in a device hierarchical data model. Several metadata items describing a DP are identical to the ones describing a DC:
  o Optional general properties: name, description, version, PkgType.
  o Platform-specific properties useful for deployment: PkgID (DP), PkgURL, ID (DC), data.

• Software lifecycle management operations:
  o For DPs (see Figure 5-5): Download, DownloadInstall, DownloadInstallInactive, Install, InstallInactive, Remove. Some primitives are defined as "composed" in SCOMO specification: DownloadInstall, DownloadInstallInactive. The rationale may be to better match the operations defined in various software platforms or define shortcuts in order to speed up the networked process. The following citation seems in favour of the second reason: "When a Composed Primitive is executed, two state transitions happen in the Device. For example if DownloadInstall is executed, a Deployment Component transits from Not Downloaded State to Delivered State after successful download procedure. It transits to Active State after successful installation procedure. If the latter processing fails it remains in previous state and the second state transition does not happen."
  o For DCs (see Figure 5-6): Activate, Deactivate, Remove. Deployment units can be explicitly activated or deactivated in this specification. The Deactivated state represents a state where no applications can use the DC (similarly to the UPnP SMS Unresolved state). The explicit activation makes the contained services and resources accessible to applications and the end-user. The SCOMO activation may correspond to an explicit resolution action in the UPnP SMS diagrams with EUs startable only when the DU becomes resolved (Installed state).
  o For SCs: No operation is defined.

³ Moreover, the inactive state matches more the Unresolved state of the UPnP specification than the Inactive one. Indeed, this state prevents resources to be accessed by other software entities: "The main goal of Inactive state is to minimise the downtime of Deployment Component management operations. Interference with external events (e.g. some end-user actions) could disturb or even block some management tasks. Inactive state is a powerful concept when implementing fault tolerant systems it enables controlled management operations. e.g. safe removals of Deployment Components from runtime-environment."

Copyright UPnP Forum © 2012. All rights reserved.
Software entity states:

A. Of DPs (see Figure 5-5): Not Downloaded, Delivered, Installed, Removed. Quoted in the specification: "Delivered State enables “deliver-first-install-later”-like use cases e.g. updates of mobile office solutions requiring all the components to be activated immediately after back-end update. In this case the Delivery and Deployment are discrete”.

B. Of DCs (see Figure 5-6): Inactive, Active, Removed.

C. Of SCs: No state is defined.

Events: Alerts are defined for every state change.

Deployment Unit repositories: The inventory of DPs in the "Not Downloaded" state lists the DPs that are available for delivery. The inventory of DPs in the "Delivered" state lists the DPs that are available for installation.

Execution Unit repositories: A DC inventory is also specified in the device data model.

6 Software Data Model (Normative)

Software Data Model is OPTIONAL for any SMS implementation. Implementations which choose to provide additional information to control points can implement the Software Data Model and support CMS to access this Software Data Model. Refer to the CMS [CMS] document for column definitions and notations used in the below tables.

7 Changes In newer version (Informative)

Support for new Security Feature was added. This resulted in the following actions and state variables to be added newly in SoftwareManagement:2 service

**Action:**
getACLData()

**State Variable**
A_ARG_TYPE_ACL
